Proulx, Donald

David Chicoine
Department of Geography and Anthropology, Louisiana State University, Baton Rouge, LA, USA

Basic Biographical Information

Donald A. Proulx (Fig. 1) (born 27 May 1939 [Milwaukee, WI, USA]) is an American anthropological archaeologist specializing in the art and

Proulx, Donald, Fig. 1 Donald A. Proulx (Credit: D. A. Proulx)

P

material culture of the ancient complex societies that developed in the Central Andes, in particular that of the Nasca society that emerged on the south coast of Peru. His fieldwork has mainly involved systematic surface surveys of the Nepeña and Nasca valleys, while his analyses and writings have emphasized cultural historical reconstructions, settlement patterns, ancient pottery, and visual arts.

Proulx's interest in archaeology and Native American cultures developed at an early age during visits to the Milwaukee Public Museum and through reading books during his teenage years at Marquette University High School. After a stint in engineering, he enrolled in anthropology at the University of Wisconsin-Milwaukee (1959–1961). During his undergraduate years, Proulx participated for the first time in archaeological fieldwork at Point of Pines, a thirteenth-century AD pueblo site where the University of Arizona held its field school under the direction of Emil Haury and Raymond Thompson. In Wisconsin, he volunteered at the Milwaukee Public Museum and worked in the anthropology section under the guidance of Lee Parsons and Robert Ritzenthaler. At the museum, Proulx first got acquainted with Peruvian artifacts and became particularly intrigued with Paracas and Nasca vessels from the south coast of Peru.

Upon graduating with a BS in anthropology in 1961, Proulx was admitted into the graduate program at the University of California, Berkeley. There he benefited from the mentorship of leading Andeanist John H. Rowe. Proulx first visited Peru in 1963 when he assisted Rowe in the field in the Ica Valley on the south coast as well as at Chavín de Huántar in the north central highlands. Back in Berkeley, he studied Nasca pots in the Max Uhle collection (Proulx 1970). Proulx also visited the Field Museum in Chicago to analyze Peruvian pots collected by Alfred Kroeber. In 1965, Proulx defended his dissertation on "Local Differences and Time Differences in Nasca Pottery" in which he inferred Nasca sociopolitical organization based on the seriation of pottery from Phases 3 and 4 of the Nasca style from two different south coastal valleys (Ica and Nasca) (Proulx 1968a). During his years at Berkeley, Proulx was influenced by several key figures in anthropology including J. Desmond Clark, John Graham, Sherwood Washburn, Theodore McCown, Eugene Hammel, Gerald Berreman, Robert Murphy, Dell Hymes, Lawrence Dawson, and Dorothy Menzel.

Proulx joined the anthropology faculty at the University of Massachusetts Amherst in 1965 where he taught until his retirement in 2002. At Amherst, he taught a variety of courses on archaeology, pottery analysis, Andean ethnohistory, and South American prehistory. Proulx also advised both undergraduate and graduate students and held various administrative positions including Chair of the Department of Anthropology (1975–1978, 1999–2000) and Director of the Latin American Studies Program (1980–1992).

Proulx returned to Peru in 1967 to initiate the first systematic survey of the Nepeña Valley on the north central coast (Fig. 2). The surface inventory was originally to be part of a broader archaeological initiative planned by Junius B. Bird of the American Museum of Natural History which aimed at excavating the monumental center of Pañamarca. While this large-scale excavation project never materialized, Proulx continued the Nepeña research during the years 1967, 1971, and 1979. During the latter year, he conducted research with his graduate student Richard E. Daggett. Daggett continued Proulx's pioneering study in 1980–1981 which resulted in

Proulx, Donald, Fig. 2 Donald A. Proulx during his 1971 survey of the Nepeña Valley (Credit: D. A. Proulx)

his 1984 PhD dissertation entitled "Early Horizon Occupation of the Nepeña Valley, North Central Coast of Peru." In total more than 360 archaeological sites were documented by Proulx and Daggett. This work helped establish the first cultural and chronological sequence for this important valley, and it resulted in a series of important publications (Daggett 1987; Proulx 1968b, 1973, 1982, 1985).

Proulx returned to the field between 1996 and 1998, when he directed survey operations in the lower Nasca Valley on the south coast. Following his retirement in 2002, he was named Professor Emeritus and continued working on publications and as a consultant for a Nasca exhibit in Tokyo, Japan, in 2006.

Major Accomplishments

Proulx's main contributions to Andean archaeology are in the realm of cultural history, systematic surface surveys, as well as the study of Nasca pottery and its imagery (Proulx 1968a, 1994, 2000, 2006). While his interest was sparked during his undergraduate years in Wisconsin, he began to systematically analyze Nasca pottery as part of his PhD dissertation work. Proulx analyzed pots from the Nasca Phases 3 and 4 of the Dawson's sequence. He refined Dawson's Phase 3 and classified it into four sub-phases. The comparative study of vessels from the Ica and Nasca valleys was used by Proulx to argue for the emergence of a centralized political entity during Phase 3 and centered at Cahuachi. This inference was based on the shift from regional homogeneous style during Phase 3 to an increased stylistic diversity during Phase 4, suggesting the loss of centralized authority at Cahuachi during Phase 4.

Since his original seriation work, Proulx has worked on building a "Nasca Archive" based on the model of the Moche Archive (see Christopher B. Donnan this volume). Proulx photographed Nasca pots in Peru, the USA, Germany, and the UK. To date the archive counts 10,000 slides representing 600 vessels. After digitization, the Nasca Archive now has 24,000 images representing pieces from over 150 museums and private collections. In 2017, this archive was donated to Dumbarton Oaks in Washington, DC, where it is available for research. In addition to a series of articles and book chapters on Nasca art, Proulx's research culminated in the publication in 2006 of *A Sourcebook of Nasca Ceramic Iconography.* He subsequently produced a series of manuscripts on Nasca visual arts and iconographies which he made available to interested scholars on an individual basis. The papers survey various topics including authenticity, human representations, monkeys, trophy heads, violence, and warfare more generally.

As a field archaeologist, Proulx is best known for his systematic surface surveys of the Nepeña and Nasca regions. In Nepeña, his pioneering work between 1967 and 1979 followed the famous excavations of Julio C. Tello in the 1930s at the ceremonial complexes of Punkurí and Cerro Blanco. Proulx's efforts were the first to yield a cultural sequence for Nepeña at a time when only the Virú Valley had been systematically surveyed. With the exception of his collaboration with Daggett in 1979, Proulx worked alone in Nepeña and did so with limited resources. The result is a testament to his diligence. In Nasca, Proulx surveyed previously undocumented portions of the lower valley. Proulx initiated preliminary surveys in 1996 and 1997 and obtained funding from the Heinz Foundation. He spent 3 months in 1998 surveying and recording 128 sites (Fig. 3).

Between 1996 and 2000, Proulx collaborated with David Johnson, a teacher, videographer, and independent scholar from Poughkeepsie, NY, on a project studying the spatial relationships between Nasca geoglyphs and sources of subterranean water. The project was funded through a grant from the National Geographic Society awarded to Johnson and involved a team of geologists and archaeologists. While the team is credited with identifying several previously unknown geoglyphs and collecting valuable geological and hydrological data, some questions remain regarding the relationship between the geological faults associated with water sources and the location of the geoglyphs.

Prous, André

Adriana Schmidt Dias
Department of History, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul (RS), Brazil

Basic Biographical Information

Born in France in 1944 and living in Brazil since 1971, the professional performance of André Prous is intertwined with the history of academic archaeology in Brazil. With a B.A. and M.A. in history from the University of Poitiers, he started his Ph.D. in prehistory in 1970 at the University of Paris I (Pantheon-Sorbonne), participating in field activities coordinated by Leroi-Gourhan and attending seminars on American settlements by his mentor Annette Laming-Emperaire at the Ecole Pratique des Hautes Études. His academic career in 1960s Paris was marked by the exchange with a first generation of Brazilian students seeking training in archaeology abroad and whom later became part of the professional staff of the leading universities in Brazil. Through a technical cooperation agreement between France and Brazil,

André Prous was hired in 1971 by the University of São Paulo to teach Prehistoric Archaeology in Department of History. That same year also began his first field activities in Brazil as part of the Franco-Brazilian Mission at Lagoa Santa (Minas Gerais State), coordinated by Annette Laming Emperaire. They excavated the site Lapa Vermelha IV until 1977 which featured buried rock panels, human burials, and datings around 9,000 years, indicating the high potential that studies of rock art in this new region could provide. In 1975, facing the possibility of returning to France to work in a center for archaeological research that was being assembled in Valbonne, Prous chose to settle down permanently in Brazil at the invitation of the Federal University of Minas Gerais, where in 1976 he founded the Archaeology Division in the Natural History Museum where he still lectures, as a full professor in the Department of Anthropology. His professional activities at this university influenced the constitution of a new generation of Brazilian researchers, especially his studies of rock art and ceramic and lithic technology, emphasizing the practice of experimental archaeology, analysis of chaîne opératoire, and functional studies. In addition, Dr. Prous was against the division of Brazilian archeology into theoretical subgroups, arguing in favor of a dialogue between the different theoretical and methodological schools (mainly of European and North American origin) which formed the pillars of archaeological science in the country. In 1981 Prous began coordinating the Franco-Brazilian Mission in Minas Gerais and has since conducted extensive archaeological survey projects in different regional contexts of Minas Gerais State such as the Serra do Cipó and regions of the upper and middle São Francisco River, the Doce River Valley, and the upper Jequitinhonha River, resulting in the identification of hundreds of sites with rock art dating back to the early Holocene.

Major Accomplishments

Interested in the meanings of the stylistic variations of Brazilian prehistoric art, André Prous developed his Ph.D. thesis, submitted in 1974, on the zoomorphic sculptures associated with funerary contexts at the southern Brazilian coast (sambaquis), conducting extensive surveys in institutional and private collections. The results of this research are published in *Les sculptures zoomorphes du Brésil et de l'Uruguay* (1977). From the stylistic comparison of sculpted art, he demonstrated the existence of regional variations also reflected in the lithic and bone industries, contributing to discussions on territoriality and the emergence of complex social contexts for hunter-gatherers specialized in the exploitation of coastal resources dating from 5,000 to 2,000 years BP. Studies by André Prous about the variety, complexity, and abundance of rock art in Minas Gerais State have shown that regional theme variation correlates with regional sequences of human occupation, providing methodological support for the establishment of complex chrono-stylistic sequences for the region. Comparisons between Brazilian regional rock art styles are among the main contributions of Prous, being its results systematized in the book *Brasil Rupestre* (2007). Also a noteworthy contribution is his *Arqueologia Brasileira* (1992), the first attempt to synthesize the Brazilian prehistory, taking as reference the contemporary research in the country conducted by different teams. Currently, André Prous has focused his interests on prehistoric art to the iconographic study of the Tupi pottery, contributing to the theoretical and methodological development and innovation in this field in Brazil.

Provenance Studies in Archaeology

Charles C. Kolb
Division of Preservation and Access, National Endowment for the Humanities, Washington, DC, USA

Introduction

A primary objective in the study of ancient artifacts is to discern where they were produced. When archaeologists, other scientists, students, the public, or children inquire about an object – "Where is it from?" – there are, of course, two answers. One is the place or location at which the object was found or discovered, for example, the context of its finding, and second, a more difficult question, what is the source of the object. The latter entails a diagnosis of the origin of the materials that comprise the object, the location, or site where it was produced or fabricated, who made it, and why and for what purposes. A related set of questions, often with complex answers, is how the object was relocated from its place of origin to location at which it was recovered. In archaeology, these questions apply as much to the composition of a pottery vessel as they do to a lithic tool or stone ornament but also to glass, metals, and textiles as other major artifact classes. To answer these questions, investigators employ tools and techniques borrowed from geology and geochemistry, particularly petrography, physicochemical studies, and stable isotope analyses. A majority of archaeological sourcing studies are devoted to earthenware ceramics, pottery, porcelain, and related objects made from clay as well as stone or lithic materials, notably obsidian, marble, chert, flint, and steatite. Notable achievements have been made in the analysis of glazes and glass, but there has been limited success in sourcing of other materials such as metals and especially organic substances including textiles, plant fibers, dyes, pigments, oils, tars, protein residues, amber, jet, and bone.

Definition

Provenance (noun, "origin," plural provenances), from the Middle French word *provenant*, present participle of *provenir* ("to come from" or "arise"), ultimately from the Latin *provenio* (to come forth), denotes the origin or source of an object or idea or may indicate its history of ownership. The term was originally used in art history and antiquities to designate the ownership of artworks but is now employed in similar senses in a wide range of fields, including science, computing, and archaeology.

Historical Background

The concept of provenance has been employed in archaeological research for more than 160 years and originally connoted an object's "findspot" or to indicate the source of raw materials or the location of the manufacture of an object, such as in a workshop (Wilson and Pollard 2001: 507).

Charles C. Kolb retired.

Pioneering research by European chemists led to the acceptance of the concept that some chemical property of an inorganic archaeological artifact could be considered characteristic of the raw material source of the object; hence, the concept of "chemical fingerprinting" was born. Beginning in the 1960s, the chemical provenance of ceramics and other inorganic materials and some organic raw materials were analyzed and aided by the mathematical treatment of data sets and the manipulation of multivariate data. Professional archaeologists embraced fingerprinting as a major analytical tool as they had Willard Libby's radiocarbon dating five decades ago.

In the archaeological literature, the terms provenance and provenience are sometimes used interchangeably, but this is not always the case. Price and Burton (2011: 213–214) oversimplify it, suggesting provenience as "birthplace" and provenance as "resume." Historical archaeologists designate provenance as "the source of geological materials" and provenience as "the location where an artifact was recovered" (Hauser 2008: 162). There are potential semantic differences as, for example, the spelling of the term "archaeology" is used predominantly in the English-speaking world including North American academic institutions, but the term "archeology" tends to be a post-World War II spelling found in more recently established universities and publications oriented to anthropological archaeology. Provenance is used in the United Kingdom and much of the Old World to mean "place of origin."

In North America, provenience has largely replace provenance because for former is restricted to in situ location at the time of the discovery rather that the historical chain (origin to the present) employed by art historians and museums. Provenance may be used to explicate any artifact recovered archaeologically or any fossil recovered by paleontologists and in computer processing to indicate the history of data in a database record. In a review of nearly 700 articles on "provenance" appearing in the British journal *Archaeometry* (1957–2011), one finds the use of archaeology/archeology as well as provenance/provenance; some North American authors employ both spellings, archaeology or archeology, while provenience tends to be employed by North American scholars to mean either the artifact's context or location or its history. A review of a similar set of more than 250 articles on "provenance" in the *Journal of Archaeological Sciences* (1974–2011) and nearly 50 in the *American Journal of Archaeology* (examined 1960–2011) reveals a mixed use of "provenance" to mean origin of raw materials and/or the location where an object was found.

In archaeological and ethnographic studies in North America, the term provenience is used somewhat similarly to "provenance," but readers are advised to determine if an author uses the terms as synonyms or differentiates them by employing provenience to describe the context in three-dimensional space in which an artifact was recovered and using provenance to designate the source(s) or raw materials used in making the artifact and the object's documented history. The "provenience postulate" (Weigand et al. 1977: 24), initially suggested in a study of turquoise sources, is a significant element in the study of the origin of archaeological materials and states that chemical differences within a single source of material must be less than the differences between two or more sources of the material if they are to de differentiated. This means that if a source is determined to be chemically distinct, materials from it that have been moved some distance from that source would share the same chemistry and can be determined. Ideally, this would (1) involve a natural material that has not been altered after extraction from the source, (2) that there are a small number of potential sources, (3) that the investigator has adequate samples from each source to be able to assess compositional variability, and (4) that there are one or more elements or compounds adequately distinguishes the sources. Hence, obsidian is a more "ideal" material than pottery clays, glass, and metals, since clays can be mixed with other clays, glass cullet (broken recycled glass) and metals – particularly copper, silver, and gold – can be mixed with like materials from widely different sources during remanufacturing processes, and metals can be mixed to produce alloys such as bronze. In addition, comparative

techniques, expert opinions, and the results of other scientific analyses may also be used to support the history of an object, but establishing provenance is essentially a matter of documentation.

Archaeological Research

Archaeological research entails the documentation of the precise location of sites, architecture, artifacts, and raw material sources. Placing these in a three-dimensional context and relating the coordinates to a master datum and the use of Cartesian coordinate were traditional practices now supplanted by GPS and GIS. The Global Positioning System (GPS), a space-based global navigation satellite system (GNSS), provides location and time information anywhere on the Earth, while a geographic information system (GIS) also known as a geographical information system or geospatial information system is a merging of cartography, statistical analyses, and database technology that is designed to capture, store, manipulate, analyze, manage, and present a variety of geographically referenced data. Precise locational data for artifacts and raw material resources have become a hallmark of modern archaeology and is a form of "provenance."

The Provenance Hypothesis

The traditional way of determining the geographical source of ancient pottery has been to map the spatial occurrences of pottery styles. For the historic eras, this poses minimal difficulty because historical and archival documents may locate kiln sites or production areas, but for much of prehistory information on production locales, the types of pottery fabricated there and the sociocultural and economic parameters associated with production are elusive. The criterion of abundance, gravity model, or other paradigms have provided assistance, but for the past seven decades, methodologies derived from geology and petrography and a variety of physicochemical approaches have been employed to locate potential places of origin by characterizing the composition of the artifacts with known sources of the raw materials used to fabricate the objects. Provenance studies on pottery, obsidian, turquoise, steatite, chert, and jade have been especially valuable but rest upon assumptions in the "provenance postulate" which is normally formulated in terms of chemical composition. Simply put, the postulate assumes that differences between distinct sources of raw materials may be recognized analytically and that the compositional variations will be greater between the sources than within the sources. Rice (2015: 342–347) provides a valuable, in-depth, and well-documented discussion of ceramic provenance and reviews chemical and petrographic methods, the creation of reference groups, the use of instrumentation and statistics, the selection of elements for analysis, and comparing sherds and clays. In a more widespread treatment of the topic, Sayre (2000) discusses structure, raw materials and inclusions, multivariate statistical analysis, and characterization through ratios of stable isotopes.

Alice Hunt in her assessment of "provenance" (Hunt 2012) points out that the multidisciplinary nature of the archaeological sciences "inevitably leads to an incomplete understanding or misunderstanding of the technical, theoretical, and methodological limitations of the parent fields" (physical, social, and earth sciences). An imperfect understanding of these limitations may lead to the misinterpretation and miscommunication of scientific data because of the lack of a unifying vocabulary. She goes on to differentiate provenance as currently used in archaeology, the geological sciences, and the archaeological sciences. Using ceramic manufacture as an example, Hunt contends that the geological sciences are concerned with "origins or sources of sediments and detrital materials," while archaeological sciences focus on the "raw material used to manufacture artifacts." *Archaeometric sciences* could be a synonym for either or both in locating the sources of materials and creation of material culture.

Wilson and Pollard (2001: 507–508) indicate that scientific provenance studies rest on six basic assumptions (presented in abbreviated form here): (1) that some chemical or isotopic characteristic of

the geological raw materials is carried through unchanged into the finished object, (2) that the fingerprint varies between potential geological sources available in the past and that this variation can be related to geographical occurrences of the raw material, (3) that such characteristic fingerprints can be measured with sufficient precision in the finished artifacts to enable discrimination between competing potential sources, (4) that no "mixing" of raw materials (before or during processing) or that the mixing can be accounted for adequately, (5) that postdepositional processes either have a negligible effect or that the alteration can be detected, and (6) that any observed patterns of exchange or trade of the finished products are interpretable in terms of human behavior.

Provenance Studies of Archaeological Materials (Raw Materials and Finished Products)

Provenance studies on stone, ceramics, and metals account for the vast majority of all archaeological provenance analyses:

- *Lithics/stone: raw materials*. Lithic raw materials may occur in outcrops or geological beds or as nodules in stream beds. Provenance studies have been undertaken on a wide variety of raw materials and artifacts including alabaster, basalt, chert, chlorite, flint, granite, greenstone (jadeite and nephrite), hematite, limestone (blocks and plaster), magnetite, marble, obsidian, quartzite, rhyolite, sandstone, schist, steatite (soapstone), and turquoise. Because the extraction and fabrication techniques of lithic production do not alter significantly the chemical composition, lithics provide the best material by which to test the provenience hypothesis. Artifact reuse, exposure to heat, postdepositional processes, and storage in archaeological repositories or museums are not likely to modify the bulk chemical composition; hence, stone is theoretically an "ideal" material for provenance assessment. Lime plaster, cement, and concrete derive from rock sources and present complicating issues in provenance studies but not as complex as ceramics (Wilson and Pollard 2001; Tykot 2004; Lambert 2005).
- *Ceramics/pottery: finished products*. Provenance studies have been conducted on earthenware, stoneware, protoporcelain, and porcelain which may occur in various types and classes of ceramic materials: domestic/utilitarian and ritual pottery containers, figurines, spindle whorls, earspools, and other objects. Unlike stone sources or outcrops of source materials, clay is a complex product of rock mineralogy and subject to weathering and found in a variety of locations worldwide. Hence, few chemical studies have directly linked pottery vessels with specific clay sources. Clays being transported long distances from sources may contain naturally occurring organic or inorganic aplastics or tempers, or organic or inorganic materials may be introduced purposefully or by accident during the preparation of the clay. Heterogeneous clays from different sources may be mixed, levigated, and wedged, and pottery may be hand-built or wheel-thrown. The size and complexity of the manufacturing process – household production by one fabricator versus creation by multiple artisans each responsible for one step in a multiphase process versus a factory or industrial level of fabrication – complicate the ability to precisely define ceramic provenance (Tykot 2004; Kolb 2008, 2011; Reedy 2008; Rice 2015; Marlowe 2016).
- *Glass: finished products*. Products that have been studied for provenance include beads, containers and other vessels, faience, glazes, ingots, ornaments, tesserae, and window glass. Glass may have been a by-product of the technology of either glazed ceramics or metals. Ancient pyrotechnologies were unable to reach silica melting temperatures so that a modifier or flux derived from plant or animal sources was employed to lower melting points. Like ceramics, the composition of glasses and other vitreous silicates affects provenance because of the heterogeneous nature of the original raw materials used in production, the use of cullet, the addition of colorants or decolorants, and that containers used to hold

molten glass is itself subject to flux and add impurities. As a result, the scientific assessment of glass provenance has had mixed success (Wilson and Pollard 2001; Lambert 2005; Paynter and Dungworth 2011).

- *Metals: raw materials*. These include native copper, copper alloys, gold, lead, silver, and tin. Metals were among the earliest materials submitted for scientific provenance analyses but, like glass, suffer from the same issues of heterogeneous raw material origins, recyclability, purposeful or accidental mixing, and the creation of desired alloys, as well as high temperatures that alter trace element compositions and the discard of unwanted material removed as slag. In addition, fabrication procedures – cold hammering, annealing, joining, and casting – provide additional issues for determining provenance (Wilson and Pollard 2001; Tykot 2004; Lambert 2005).
- *Other materials: raw materials and finished products*. The sources of amber, antler, bitumen, bone, dyes, horn, ivory, jet, pitch, resin, tar, and various organics such as hair and fibers have been analyzed. Baltic amber was characterized in the 1980s and can be distinguished from non-Baltic sources and imitations. Varying degrees of success have been reported with the studies of jet and ivory, while analyses of human bone and teeth have been useful in determining human migrations, and the assessment of herd animals (particularly sheep, goat, and cattle) has also focused on animal origins and movements. In addition, provenance studies of woolen textiles have increased dramatically during the past decade (Wilson and Pollard 2001; Lambert 2005).

Analytical Methods (Thin-Section Petrographic Analysis, Optical Mineralogy, or Optical Petrography)

The macroscopic analysis of lithics, ceramics, and other clay objects is the initial step in analysis, closely followed by binocular and petrographic thin-section microscopy, derived from the geological sciences or materials science, which has been used for more than seven decades. Petrographic analyses in the 1920s led to the identification of stone sources used at Stonehenge. The technique remains an especially viable tool in the assessment of paste characteristics and ceramic provenance, playing a "crucial role" in provenance studies. The earliest research on pottery dates to Anna Shepard in 1932. Thin-section petrographic analysis (T-S-P), optical mineralogy (OM), and optical petrography (OP) are flexible techniques that can assist in characterizing textural aspects of clays, vessel, and/or sherds from the analysis of thin sections. Raw clays may naturally contain organic and/or inorganic aplastics, or temper may have been added during processing and/or by the potter during the mixture of different clays. These cultural factors complicate T-S-P and other physicochemical analyses such as INAA (Neff 1992, 1998). Petrographic microscopy is the only technique that can describe individual mineral grains within a vessel or sherd. On the basis of cost-effectiveness, ease of sample preparation, and simplicity of analytical procedure, the petrographic microscope offers the best method for identifying and classifying mineralogical compositions of ceramic pastes and relating these to their respective potential aplastics, especially those of inorganic origins. The thin sectioning of sherds or portions of ceramic artifacts (vessels and figurines) and the study of prepared specimens by petrographic microscopy have been demonstrated to be especially useful when the clay minerals and aplastics of a limited geological or geographical distribution are identifiable within the clay body. In these instances, it is a relatively easier task to locate an area or areas from which, based on clay and/or aplastic and/or mineral temper components, a particular ceramic artifact is most likely to have originated. Reedy (2008) has written the most recent salient assessment on thin-section petrography. Drawbacks include that the technique is destructive of the original object since the analysis of ceramics or lithic material requires a thin section of at least 1 cm^2 for analysis. In addition, there are limitations on mineral

identification, notably that minerals <100 μm in diameter cannot be readily identified, and there are difficulties identifying opaque minerals. However, the procedure has been useful in characterizing ceramic types and wares especially in contexts where comparative petrographic data are lacking – such as in Central Asia (Kolb 2008).

A Summary of Major Provenance Methods

The summary format derives from Tykot (2004) and methodological data from Cilberto and Spotto (2000), Glascock and Neff (2003), Goffer (2007), Hunt, ed. (2017), Lambert (2005), Pollard et al. (2007), Pollard and Heron (2008), and Wilson and Pollard (2001) as well as from a review of provenance studies reported in *Archaeometry* (1957–2017), *Journal of Archaeological Sciences* (1974–2017), and *American Journal of Archaeology* (1960–2017). Other relevant journals that publish provenance studies include *Geoarchaeology: An International Journal* and *Journal of Archaeological Research*.

Examples from the literature are noted.

- *AAS*: Atomic Absorption Spectroscopy or *OES*
  - Materials: stone, ceramics, glass, metals. Analyte: solution.
  - Bulk chemistry: good; trace elements: very good (70+ elements).
  - Superseded in the last decade by XRF.
  - Examples: prehistoric pottery from Oklahoma; Maya ceramics from Guatemala.
- *EPMA*: Electron Probe Microanalysis
  - Materials: stone, ceramics, glass, metals. Analyte: solid.
  - Bulk chemistry: excellent (surface); trace elements: low sensitivity.
  - Similar to SEM which has a higher sensitivity.
  - Examples: stone ballast to elucidate Mediterranean Sea trade routes; vitrified Peruvian wares; ancient Sudanese ceramics; Etruscan pottery.
- *FTIR*: Fourier Transform Infrared Spectrometry
  - Materials: stone, ceramics, glass, metals, organics, burned bone. Analyte: solid.
  - Bulk chemistry: good; trace elements: very good.
  - Examples: southern Ontario chert sources; dyes used on silk (Prussian blue); dyes used on Greek ecclesiastical textiles (sixteenth to nineteenth century); differentiating Italian and Baltic sources of amber; sources of fats and oils used in Greek perfumes; wine residues in amphorae.
- *GC*: Gas Chromatography, *HT-GC* (High Temperature GC), *HT-GS-MS* (HT-MS with Mass Spectrometry)
  - Materials: organics (hair, fur), resins, oils, fats, lipids, esters. Analyte: gas.
  - Some gas chromatographs can be connected to a mass spectrometer which acts as the detector.
  - Examples: sheep hair/wool discerning Scandinavian origins; terpenoid resins identifying Yemeni trade routes; pine resins on Great Basin pottery; Mediterranean Bronze Age perfumes; beeswax in Greek ceramics; bitumen sources used by the Mesoamerican Olmec (1200 BCE); sources of jet artifacts in the United Kingdom.
- *ICP-AES*: Inductively Coupled Plasma (Spectroscopy)-Atomic Absorption Spectroscopy
  - Materials: stone, ceramics, glass, metals, wine. Analyte: solution.
  - Bulk chemistry: very good; trace elements: excellent (a large number of elements).
  - Examples: Aegean obsidian; Nuzi ware from Syria.
- *ICP-MS*: Inductively Coupled Plasma-Mass Spectroscopy
  - Materials: stone, ceramics, glass, metals, serum blood, urine. Analyte: solution.
  - Bulk chemistry: very good; trace elements: excellent (50+ elements); it is replacing INAA.
  - Examples: steatite sources in Crete; Egyptian ceramics; sources of French porcelains; copper alloy artifacts from Tepe Yahya, Iran; Sassanian glass vessels from Iraq.

- *ICP-OES*: Inductively Coupled Plasma-Optical Emission Spectrography
  - Materials: stone, ceramics, glass, metals. Analyte: solution.
  - Bulk chemistry: very good; trace elements: very good.
  - Examples: third millennium BCE Iberian ceramics; East Asian storage jars.
- *INAA/NAA*: Instrumental Neutron Activation Analysis
  - Materials: stone, ceramics, glass, metals, amber. Analyte: solid/powder
  - Bulk chemistry: very few elements; trace elements: excellent.
  - Since 1967 it has been commonly used in provenance analyses and is a powerful quantitative analytical technique with application in a broad range of disciplines including agriculture, archaeology, geochemistry, health and nutrition, and environmental monitoring. Because of its sensitivity, great accuracy and precision, and versatility, the technique is a suitable method for analyzing many different types of samples (Glascock and Neff 2003: 1516; Neff (ed.) 1992). Thousands of analyses have been undertaken on lithics, ceramics, and metals.
  - Examples: widespread use on obsidian artifacts and sources in Mexico, Guatemala, Peru, central and eastern Europe, the Aegean Islands, Sardinia, Turkey, New Zealand, and New Guinea; North American pipestone artifacts; chert sources in Belize; Samoan basalt; Etruscan marble. Commonly used since 1957 in ceramic and clay figurine analyses in the Mediterranean region (e.g., Tarsus, Rhodes, Corinth, Mycenae, Cyprus, and Italy); Samian ware; Basin of Mexico ceramics; Yuan Dynasty porcelains. Sourcing Sassanian silver in Southwest Asia; European blue glass trade beads in Ontario, Canada (c. 1660 CE); pigments in oil paintings (Rembrandt, Vermeer, and Van Dyck).
- *LA-ICP-MS*: Laser Ablation-Inductively Coupled Plasma (Spectroscopy)-Mass Spectrometry, *TOF-LA-ICP-MS* (Time-of-Flight LA-ICP-MS)
  - Materials: stone, ceramics, glass, metals. Analyte: solution.
  - Bulk chemistry: very good; trace elements: excellent, high sensitivity (70+ elements).
  - Requires small samples and leaves minimum scarring on the artifact; see Dusseubieux et al. (eds.) (2016) for details.
  - Examples: used since 2002 to analyze Aegean obsidian artifacts and architectural limestone used in Classic period Teotihuacan, Mexico (200–600 CE). In ceramics: Colonial Mexican pottery; Samoan wares; differentiating Hohokam and Patayan pottery in Arizona. Glass: Near Eastern bead sources (Mesopotamia, Egypt, and Greece); Italian glass mosaic tesserae. Metals: copper alloys at Tepe Yahya, Iran; production loci of Roman coins in Europe.
- *LC*: Liquid Chromatography, LC-MS (LC with Mass Spectrometry)
  - Materials: resins, dyes, sera, blood, oils, fats, lipids, esters, wine. Analyte: liquid.
  - Examples: ancient dyes from the eastern Mediterranean (Tyrian purple from *Murex* sea snails); textile dyes from Southwest Asian Bronze and Iron Ages; the Shroud of Turin; beeswax in the Aegean. LC-MS is effective in characterizing wine residues in Egyptian pottery and beer residues from Southwest Asian ceramics.
- *M/S*: Mössbauer (German: Mößbauer) Spectroscopy
  - Materials: stone, ceramics, glass, metals. Analyte: solid/powder.
  - Similar to NMR spectroscopy, M/S probes minute changes the energy levels of atomic nuclei.
  - Examples: Peruvian ceramics (Moche, Nazca, and Inka).
- *OCL*: Optical Cathodoluminescence
  - Materials: stone, ceramics. Analyte: solid/powder.
  - Bulk chemistry: good; trace elements: very good.
  - Examples: differentiating local from imported Neo-Assyrian palace ware

(934–610 BCE) based on quartz grain analysis.

- *OES*: Optical Emission Spectroscopy or **AES**
  - Materials: metals. Analyte: solid/powder.
  - Bulk chemistry: very few elements; trace elements: fair/good.
  - Examples: copper alloys in Mesopotamia; steel and cast iron in European artifacts.
- *PIXE/PIGME*: Proton Induced X-Ray/Gamma Ray Emission
  - Materials: stone, ceramics, glass, metals, organics. Analyte: solid.
  - Bulk chemistry: very good (surface analysis); trace elements: fair/good
  - Examples: gold and silver coins from Southwest Asia; East Asian storage jars; obsidian from Chiapas, Mexico; South African ostrich eggshell.
- *R/S*: Raman Spectroscopy
  - Materials: stone, ceramics, glass, metals, liquids, gases. Analyte: solid, liquid, gas.
  - Examples: clay types in Argentinian pottery (900–1200 CE).
- *SEM*: Scanning Electron Microscopy, *SEM-EDS* (SEM with X-ray Detector), *SEM-WDS* (SEM with Wavelength Dispersive X-ray Detector)
  - Materials: stone, ceramics, glass, metals, textiles. Analyte: solid.
  - Bulk chemistry: good (semiquantitative); trace elements: none.
  - SEM-EDS has low sensitivity but identifies small inclusions <10 μm in diameter; higher sensitivity with SEM-WDS.
  - Examples: microstructural, microtextual, and sintering analyses of Iberian ceramics (third millennium BCE); Nuzi ware distribution (1600–1200 BCE); origins of sheep hair/wool (Scandinavia and New Zealand).
- *SIRA*: Stable Isotope Ratio Analysis
  - Materials: marble, metal, bone, teeth, organics, lead-based pigments. Analyte: solid/gas.
  - Isotope ratios: C, N, O, S, H, He.
  - Examples: Italian marbles and Aegean sculptural stone.
- *SIR*: Strontium Isotope Ratios
  - Materials: organics, textiles, leather, bone, teeth, shell. Analyte: solid.
  - Isotopes: $^{87}Sr/^{86}Sr$ ratios.
  - Important in reconstructing human and animal migration routes.
  - Examples: sheep hair/wool (Scandinavia); Oaxacan and Gulf Coast migrants to Teotihuacan, Mexico (200–600 CE).
- *TIMS*: Thermal Ionization Mass Spectrometry
  - Materials: stone, metals, glass, bone. Analyte: solid/gas
  - Heavy elements: Pb, Sr, Nd.
  - Examples: Byzantine and early Islamic glass sources (Egypt, Syria, and Palestine).
- *XRD*: X-Ray Diffraction
  - Materials: stone, ceramics, glass, metals. Analyte: solid/powder.
  - Bulk chemistry: excellent (surface analysis); trace elements: very good.
  - Examples: ceramics: Asia Minor terra-cotta figurines; Iranian, Iberian, and Etruscan pottery; Chinese porcelains.
- *XRF*: X-Ray Fluorescence, *ED-XRF* (Energy Dispersive-XRF)
  - Materials: stone, ceramics, glass, metals. Analyte: solid/powder.
  - Bulk chemistry: excellent (surface analysis); trace elements: excellent.
  - Hundreds of studies have been undertaken on lithics, ceramics, glass, and metals. High-precision XRF analysis does not require a nuclear facility and is preferable to INAA in terms of the ease of sample preparation and analytical procedure. The greater effectiveness of high-precision XRF than INAA in this provenance study is a result of the different array of elements measured and the higher precision obtained for certain elements by XRF. Portable (or handheld) X-ray fluorescence (pXRF) spectrometry has become common for the geochemical characterization of obsidian artifacts and ceramics; see Shackley (ed.) (2011) for details.
  - Examples: lithics: andesite (Mid-Atlantic region of the United States); basalt (Neolithic to Roman era millstones in the Mediterranean region); jasper (Japan and

Mid-Atlantic region of the United States); limestone and plaster (Mesoamerican Classic period Teotihuacan and Postclassic Mexica Aztec); obsidian (New Mexico and the Basin of Mexico). Ceramics (since 1999): Tikal, Mexico; southwestern Iran; Attic coral red slips; Rio Grande glaze paint pottery trade; French white earthenwares (1755–1820). Glass: Mesopotamia; Roman glass in Britain; medieval blue soda glass. Metals: Athenian coins; Roman coins in the United Kingdom; cold-worked copper in Upper Great Lakes North America; pewter flatware in Europe (thirteenth to sixteenth century); Ife and Benin West African bronzes; differentiating native North American from European imported copper.

- *XRPD*: X-ray Powder Diffraction
  - Materials: stone, ceramics, glass, metals. Analyte: solid/powder.
  - Bulk chemistry: excellent (surface analysis); trace elements: very good.
  - Examples: crystalline phases of ceramics during firing (Balearic Islands, 1700–850 BCE).

Key Issues and Future Directions

Early provenance studies focused on the use of one or two methods in combination, such as thin-section petrography (T-S-P) and INAA. The literature review indicates that currently up to a half-dozen methods may be employed in combination to answer a variety of questions. A few characterization examples:

- Flint by ICP–SFMS and MC-ICP-MS
- Marble by T-S-P, PIXE, EMPA, and SIRA
- Lime plaster by T-S-P, SEM-EDS, XRF, and LA-ICP-MS
- Clay cooking vessels by T-S-P, XRF, INAA, XRD, and SEM. XRF, ICP-MS, XRD, and EPMA. ICP-AES, SEM, and XRD. T-S-P, SEM-EDS, INAA, R/S, and X-ray (vessel structure) plus replication studies
- Amphorae by T-S-P, XRD, XRF, and EPMA
- Ceramic crucibles by binocular microscopy, T-S-P, XRD, ICP-MS, ICP-AES, SEM
- Organic dyes by SEM-EDX and HT-GC-MS

T-S-P with computerized point counts and SEM-EDS or XRF correlated with pottery forms, surface treatments, and construction methods create a holistic approach to the thin-section analysis. The goal is to understand the advancement of manufacturing techniques, which are built upon the technical discoveries of individual potters and driven by changes in socio-cultural practices, mortuary traditions, and economics (Kolb 2011).

T-S-P is advancing through the scanning of the thin sections and sherd surfaces and adding images to searchable databases. An advantage is that these images include the entire area of the thin section (under low magnification) rather than just a single field of view as under a microscope, facilitating macrotexture studies. An advantage is that the time and expense of thin-section cutting, mounting, and grinding are eliminated, allowing data to be collected on even larger numbers of specimens for rapid characterization (Reedy 2008).

Future refinements are expected in LA-ICP-MS and XRF and work advances on new topics such as characterizing slag inclusions in iron artifacts and distinguishing sources of alloys in metal and constituents in glass. Greater precision is accompanied by the troublesome question: After great time and expense in provenance studies, do scientists provide appropriate and relevant data for archaeological interpretation? Some contend that there is too much data or too precise information (Wilson and Pollard 2001: 515).

Networking sites for scientists and researchers may also be consulted for "provenance in archaeology": *Academia.edu*, *ResearchGate.net*, and *Google Scholar* – <https://www.academia.edu/>, <https://www.researchgate.net/>, and <https://scholar.google.com/>. Current contents (July 2017) list 540, ca. 500, and 101,000 citations, respectively.

Public Archaeology and Education: Present Relevance to the Past

Anna Simandiraki-Grimshaw
Department of Classics and Ancient History, University of Exeter, Exeter, UK
Bath Spa University, Bath, UK

Introduction

Public archaeology can take many forms and, in its most popular ones, aims to bridge the distance between archaeology and people who are not trained in or have had exposure to archaeological practices and their subjects. Within this interaction, education takes center stage, as it is often the goal of such interactions to educate (and at the very least satisfy the curiosity of) the public. In this entry, we will explore several ways in which education is enmeshed in public archaeology, some current debates, as well as potential future directions.

Definition

Public archaeology is any archaeological practice which involves (at the receiving end) audiences and practitioners other than trained and qualified archaeology specialists (cf. the similarly broad definition in Schadla-Hall 1999: 147). This usually (but not always) means that experts create opportunities for or invite collaborations with nonspecialists, not the other way round (i.e. it is usually a top-down approach). I take education to mean here any action which leads a person or group to acquire more knowledge than he/she/they possessed prior to the action and, as is often the case, to consequently change their understanding of a topic or even their worldview and practices. I therefore take public archaeology and education to be the relationship and entanglement of these two types of action (Franklin and Moe 2012 summarize this, helpfully in my opinion, as "archaeological literacy"; and Bartoy 2012 as "teaching *through* archaeology").

Historical Background

Archaeology as a discipline started, to a certain extent, as an educational endeavor. From their very early days, collections of archaeological (together with other) artifacts served to primarily showcase the social and cultural capital of their owners. However, archaeology's first disciplinary steps as the practice of collecting and exhibiting past material were already permeated by a desire to educate either the collector/patron about the past or his/her equals and then wider publics. Such material collections were eventually gradually configured into the holdings of public, private, and university museums. In addition, this desire did not arise only because these publics were thirsty for knowledge themselves but also because collectors and patrons, and eventually local and national governments, saw the public's education in archaeology as a service which they were morally obliged to provide and portrayed themselves as suitable to facilitate or impart it.

In time, this type of public archaeology, largely driven by museum education, diversified. It also began to include volunteering opportunities in the museum sector, public talks, and exhibitions based on public interest (e.g. in nationalist content, seasonal relevance, etc.), as well as

volunteering opportunities in the field, from site tours and community events to excavation participation. Over time, the demographic of the involved publics also broadened. Originally, only the affluent upper and aspirational middle classes entertained archaeological interests in the intellectual context of the museum or the site visit (even the Grand Tour), the latter facilitated by the "great man" or (more seldom) the "great woman." At the same time, the lower classes were engaged with archaeology in either more practical ways (e.g. as excavation workers) or in folkloric practices (e.g. using sites for pasture, local festivities or even worship, cf. Hamilakis 2009). Gradually, however, there was a general tendency for the "opening up" of museums, excavations and archaeological practice more generally on particular occasions or seasons. There was also a tendency for a better public understanding of and desire for heritage to become more widely accessible than it had been previously (for a very good overview, see Schadla-Hall 1999; Bartoy 2012; also Kehoe 2012).

This gradual "democratization" was precipitated by profound political, social, and economic events, which created the right environment for such changes. For example, the nineteenth-century nationalism and state formation in a number of locations worldwide fostered a larger appetite for new excavations, museum exhibitions, talks, and public debate about the past of these territories. Similarly, the two World Wars of the twentieth century C.E., the sociopolitical events of the 1960s and 1970s, the proactive introduction of conservation legislation, and the advent of postmodernism had an immense impact on the (sometimes radical) reconfiguration of national and community identities and especially class systems. They also created new needs and opportunities for education through public archaeology (also see discussion of the North American *Education and Archaeology Work Group* and its agenda in Franklin and Moe 2012).

At the same time, the economics of archaeological research changed significantly. In its early days (but also to some extent until now), archaeology as a discipline was sponsored, much like the arts, by wealthy patrons or governments which saw it as a sociopolitical investment, in the context of the "public service" described above. As both archaeological and public spending paradigms shifted, e.g. due to the different priorities for education, training, and public investment after especially World War II, the patron system largely migrated to the university, museum, charity and local government sectors. It also diversified to operate within a complex network of funding schemes for humanities in general, where archaeology had (and still has) to compete with a number of other "causes." Consequently, public archaeology, apart from its public service persona, had to adapt to a new role: that of a fundraiser in the age of consumerism. In other words, engaging and educating the publics became fundamental to the very existence of archaeological practice, because it meant that educational, humanitarian, and even recreational outputs needed to be seen as worthy of monetary contributions and, conversely, that the public money spent on these now demanded public accountability (cf. Schadla-Hall 1999: 152–153). This shift is also connected to a great degree to the development of mass tourism (cf. discussions in Silberman 2007; Kouri 2012). This directly funds archaeology in a number of ways, as we will see below, and so making the past relevant to the present through public archaeology education ensures the survival of both the artifacts as the subjects of research and of the discipline itself.

Key Issues/Current Debates

Archaeology engages and educates the public in diverse ways. One of those is through experts enabling people outside the archaeological and museological sector to volunteer in e.g. excavations, museum curation, open days, etc. (cf. Bridge Farm [a Romano-British site] excavation open day, Council for British Archaeology 2019). In these cases, the nonspecialists provide help as unskilled resources for the specialists, and, in return, they are trained in (often transferrable) archaeological and museological skills. They also connect with other like-minded people. This is a type of engagement which may be invited by experts, but is more proactively pursued by non-experts.

Another way in which educational engagement happens is through the organization of public talks, excavation and site tours, and school visits, as well as the creation of materials by museum professionals and excavation project directors offline (e.g. site information panels) or online (e.g. websites). In these cases, public archaeology education is actively initiated and pursued by archaeology experts with the intention of communicating their latest finds and research, or little known information, to wider audiences. This might be, as suggested above, in order to raise funds, to provide a public service, or to inspire new generations. Related to this is the presence of archaeology in the current school curriculum in any one country. It can be argued that this is a type of public archaeology education on the basis that it devolves archaeological knowledge to non-experts with the explicit purpose of educating them and of making the past relevant to their present realities. For example, the recent synergy of the Ministry of Culture and the Ministry of Education in Greece (see below) saw the involvement of several experienced archaeology specialists in the composition of high-quality heritage materials for the primary education curriculum, which was conceived (and to some extent implemented) within an interdisciplinary framework. Another example is the community archaeology outreach of Surrey County Council, which enmeshes archaeology into the (UK) national curriculum by going beyond archaeological/historical subjects, e.g. by using it in Math, English, Science, etc. (Surrey County Council 2019).

Public archaeology can also take the form of media presence, including the contribution to or even creation of documentaries, interviews to the press (e.g. local newspapers), social media presence, etc. (cf. Richardson 2013). There may be several reasons for this, and, as such, the educational outcome of this type of engagement is variable. For example, in the case of a heritage interview (cf. Cameron 2014), the educational purpose of the archaeological outreach is more explicit. In contrast, a newspaper interview might involve an archaeologist writing a column about an archaeological matter, offering a public announcement on a current excavation season or reporting on the retrieval of looted antiquities. Although these are less explicit ways in which education is imparted by the act of an archaeologist addressing the public, they do serve to create new knowledge and perhaps attitudes (e.g. about the local historical event, the excavation results, or the ethics of looting archaeological artifacts; cf. discussion on UK legislation and action in Schadla-Hall 1999: 153).

Other ways in which the public face of archaeology might educate in a top-down approach include the opportunities for the public to bring to experts found or inherited artifacts for valuation (several museums and archaeological authorities around the world hold such scheduled or ad hoc sessions). There may also be archaeologist-run workshops on subjects such as pottery dating, archaeological law (e.g. regarding metal detecting practices), and the like. They may even include the involvement of local publics in archaeological bureaucracy (e.g. when acquiring permits for building, collecting, etc.). This, of course, is not necessarily a positive educational experience, and it almost invariably alienates citizens from their archaeological authorities, especially if the bureaucracy involved is cumbersome. However, although it might be considered as perverse to consider archaeological bureaucracy as public archaeology education, I would very much argue in favor of this. Such processes do indeed educate the publics regarding the legal and ethical status of antiquities, as well as invite them to reflect on their own legal, historical, and intellectual relationship with them.

Moving toward less top-down approaches but those still involving archaeological initiative, one may observe that public educational engagement in archaeology can occur in more subtle ways which infiltrate the everyday life of the publics when the latter are not necessarily deliberately seeking archaeological education. Such initiatives might include the exhibition of artifacts, stratigraphy, etc. in public places other than museums, e.g. in the walls and rooms of the Athens Metro (Fig. 1). Urban excavation, very common in big cities with building works (see the recent example of the excavation for the HS2 rail line in London,

Public Archaeology and Education: Present Relevance to the Past, Fig. 1 Archaeology in public spaces. Archaeology (exhibits and stratigraphy) in the Athens Metro, Athens, Greece, June 2009. (All photography by and © of the author, 2009)

UK, Gov.uk 2018), can also be considered as in situ public archaeology education and sensitization of publics regarding history, archaeological method and conservation. Professionally conducted experimental archaeology is another type of such public education. One relevant commendable example has been the recent experimental archaeology carried out in Ukraine regarding the building and especially the experimental burning of the replica of a Neolithic house in the village of Nebelivka (Johnston et al. 2018; Chapman et al. in press [I thank the authors for sharing this]; Chapman and Gaydarska *pers. comm.*). In this particular case, the fieldwork, while primarily archaeological in character, incorporated a multitude of ways in which the local community interacted with the project, its researchers and its activities. Consequently, the local community was involved, and educated, in intentional, unintentional, and definitely meaningful ways.

Museums, galleries, and sites may also be used for non-archaeological reasons, such as hiring for private events (e.g. wedding receptions at the Roman Baths site and museum in Bath, UK) or concerts (e.g. at the galleries of the Acropolis Museum, Athens, Greece). In such cases these publics may also be incentivized to attend such

venues in future on their own and to seek more archaeological information. They certainly learn, in subtle ways, that these museums, galleries, and sites make the past relevant to the present by putting it in the service of modern events of personal or collective importance. Therefore, these heritage venues entwine the lives of modern people with the past in ways which are meaningful beyond the formalized circumstances of an expert-non-expert relationship. The counter-argument, of course, involves ethics and capitalism. Especially in more conservative heritage environments like Greece, antiquities are venerated to an extent (e.g. Hamilakis and Yalouri 1999) as "public right" relics and the fact that museums and archaeological services are in these cases being potentially sacrilegious is problematic. In addition, the use of antiquities as backdrops to (private) economic or other activities can be taken as a prime example of the way in which archaeology is instrumentalized for purely capitalist purposes which are irrelevant to education or heritage (cf. extensive discussions and contributions in Hamilakis and Duke 2007). We should therefore consider what social, ethical, and other repercussions this type of private capitalist normalization of public goods affords.

Public archaeology, and education within it, can additionally happen in the form of adaptations of the past by non-archaeologists, with or without the guidance of experts, i.e. where the initiative lies with the public. One obvious case is that of archaeological educational initiatives undertaken by local archaeological, heritage, educational or other associations and bodies or even by driven individuals. In these cases, education through public archaeology takes place not only in museums, sites, etc., but also in experimental environments (e.g. workshops), public events, invited lectures, the local press, theme parks, etc. (see, e.g., Cretan Thematic Park 2019). However, this type of engagement and education can often produce tensions between the expert and non-expert stakeholders, even though all sides might be well-intentioned. One common reason is that the knowledge produced and consumed under these circumstances is often not controlled or regulated by experts, resulting in competing interpretations of the past, usually utilizing different methodologies. For example, an experimental attempt at (re)creating a Bronze Age boat in Crete, Greece, a few years ago met with controversy between the project leaders (non-archaeologists attempting experimental archaeology) and archaeologists (not consulted and critical of the methods, interpretations, and results of the project; see Simandiraki 2005 for a fuller description; Fig. 2).

More "extreme" cases of archaeological educational initiatives are the public adaptations of what is often termed "fringe archaeologies" (cf. Schadla-Hall 1999: 154–155; Simandiraki-Grimshaw and Stefanou 2012). This is the use and interpretation of archaeological elements (usually artifacts and monuments) by nonspecialists for professional, personal, social, religious, and other reasons. Such practices involve some familiarity with, through study of, the material, but may significantly deviate from official interpretations and uses. These practices may range from the private collection of artifacts (e.g. through metal detecting) and neo-pagan worship (e.g. in archaeological sites or through replicas of ancient artifacts, e.g. Rountree 2006) to conspiracy theories (e.g. alien or ultra-nationalistic interpretations of material culture). Consequently, these types of knowledge, although potentially categorized as public archaeology education (insofar as they constitute archaeological knowledge arrived at by publics who self-educate), often pose a direct threat to the kinds and methods of education that the official gatekeepers of the discipline (certified professionals) espouse and impart.

Other types of adaptations might involve artistic interpretation: an artist or artistic collective may study archaeological artifacts and sites in a more or less systematic way and may thus inform their artistic practice and outputs, in which these archaeological elements are reproduced through particular filters. In this vein, we could consider high-end artistic outputs for art audiences and institutions (e.g. works by Giorgio de Chirico, Fig. 3a) or even more functionalist artistic adaptations, such as imitations of archaeological reconstructions in buildings for official (e.g. Fig. 3b, cf. Σωτηρίου and Πλιάτσικα 2015) or commercial (e.g. Fig. 3c) use.

Finally, we might consider the educational tropes encountered in public archaeology for public consumption, from state adaptations and uses of material culture to wider commercial goals. For example, in several cases the state issues official documents, such as money or stamps, based on

Public Archaeology and Education: Present Relevance to the Past, Fig. 3 Archaeological adaptations. (**a**) "Piazza Italia," oil on canvas, Giorgio de Chirico, 1913, Art Gallery of Ontario, Toronto, Canada; (**b**) the façade of the Nafplion branch of the National Bank of Greece, Nafplion, Greece, March 2010; (**c**) one of the balconies of the "Platanias Pallas" [sic] restaurant in Platanias, Crete, Greece, June 2004 ((**b**, **c**) both imitate the reconstructed concrete columns from the archaeological site of Knossos, Crete, Greece). archaeological artifacts (Fig. 4a). This practice is the outcome of a process whereby archaeological knowledge is passed onto the people commissioned to make these devices (and therefore affiliated to the state sector in some way), followed by a top-down decision of what

P

archaeological images and therefore ideas and identities to put in circulation, ultimately followed by the artifacts concerned infiltrating the public domain and eliciting query and interpretation. This process can have multiple aims and outcomes: from the state using official documents to create or enhance its own identity, to the public welcoming the use of (images of) its heritage as presently relevant educational nodes, inviting discussion, appreciation and further study.

Examples of chiefly commercial adaptations of archaeology include (but are not limited to) mass tourism and popular culture. We saw above that public archaeology education happens, among other places, in museums and archaeological sites, where people go voluntarily for education, recreation, edification, socialization, etc. Commercially speaking, this practice is inextricably linked to tourist sales (hotel bookings, travel tickets), heritage ticket sales (museums and sites admissions), the souvenir trade, etc. (cf. Silberman 2007: esp. 181–182). But how do public archaeology and education fit with these? One useful lens through which we can approach these is branding (cf. Holtorf 2007). Archaeology often attracts its publics through public outreach and brands itself as the authoritative provider of associated education and entertainment. By providing information (just facts or more educational opportunities) on websites, tourist guides, advertising, etc., it creates incentives for people to directly or indirectly partake in this type of education. Tourist bookings, which, e.g., take the initiative of including site and museum visits in package holidays even if some of their customers would not automatically do this, deliver such audiences to the archaeology sector. The latter benefits from selling tickets, souvenirs, and other materials to these audiences, directly or indirectly educating them. The local product and souvenir industries provide these audiences with artifacts which are artistic adaptations of differently digested public archaeology education (Fig. 4b, c). These industries benefit from the education of such publics when the latter buy local products and souvenirs invariably not only as recreational artifacts but mainly as tangible aide-memoirs, often for explicitly educational purposes (e.g. to build a collection). An often hidden aspect of this interdependence of sectors is the (sometimes substantial) fee that the makers of souvenirs, guidebooks, tours, alcoholic spirits, etc. must contribute to the heritage sector for the use and, to some extent, interpretation of the relevant material culture. These funds, in turn, are fed into public archaeology education in the form of updated displays, workshops and other events, curriculum provision, tourist advertising, etc. (cf. discussion in Silberman 2007).

As the outputs of all the aforementioned types of public education archaeology can serve different purposes, which may or may not be archaeological, they are not usually judged by how accurately (according to the specialists) they have reproduced the archaeological knowledge gained, but by how they have interpreted the *spirit* of the artifacts, monuments and sites they have used, and so how they contribute to an aesthetic and humanistic dialogue between past and present.

International Perspectives

The author's specialization lies in Greek (especially Bronze Age) archaeology. My experience is also principally rooted in the archaeology, museum and education sectors of Greece and the UK. Consequently, I have been actively involved in practices and debates regarding public archaeology education in both countries. I have also been informed by examples from other countries and heritage sectors through collaborative and research work. From my point of view, therefore, there are a number of examples (in addition to the aforementioned ones) of how the past can or may be made relevant to the present.

As mentioned above, one such example was the recent synergy between the Ministry of Culture and the Ministry of Education in Greece. This was called the "Melina Educational Programmes" (after the late Melina Mercouri, actress, activist and politician). It aimed at a more holistic redesigning of the curriculum, in which archaeological education per se, and as contributions to other subjects, played a vital role. Similar

archaeological education initiatives include educational materials created and events run by museums and archaeological projects with the intention of being integrated to the current school curricula (e.g. the Ashmolean Museum, Oxford, UK; the Acropolis Museum, Athens, Greece; Stonehenge, UK). The educational tropes, approaches and interpretations in such public archaeology pedagogies may be different, depending on the country's archaeological and educational traditions and practices (cf. discussion in Kehoe 2012: esp. 548). For example, there is a clear difference of approach between Greece and the UK in how local heritage is communicated, taught and interpreted. More emphasis is given to local identity in Greece and to multicultural/multitemporal perspectives in the UK. For nonschool learners, public archaeology education in Greece is (or at least has the semblance of) a more top-down process: the heritage sector either imparts knowledge (lectures, guided tours, excavation open days, etc.) or brands such knowledge as the aspirational goal of those who want to be educated archaeologically (e.g. through specialist language in museum displays and media releases). Public archaeology education in the UK is (or at least has the semblance of) a more grassroots process: the heritage sector either aligns itself more often with contemporary topics, especially in order to attract funding from funding bodies, or projects a more "industrialized" image of archaeological practice (cf. contract archaeology), designed to instill in the public a sense of education acquired through scientific labor. In fact, a more integrated heritage-tourism-education model can be discerned in the case of the UK rather than that of Greece (cf. in-depth policy discussion in Kouri 2012), especially as far as funding, cultural sustainability and conservation are concerned.

There are several issues which arise from the educational interaction between archaeology and its publics, and these precisely concern if and how the past is made relevant to the present (cf. McManamon 1991; McGill 2010). These issues, of course, are encountered in a number of countries around the world, but my examples here concern the two countries I am most familiar with. One such issue is whether archaeological educational intentions can (or should) be disentangled from non-archaeological (e.g. political) agendas. The Parthenon/Elgin Marbles, a set of sculptures from the Parthenon in Athens, Greece, is a very famous and still highly controversial example (see "▶ Parthenon (Elgin) Marbles: Case Study", in the entry by Stefanou) which involves the heritage (and politics) sector of Greece and the UK. The two countries have opposing views as to the legal status and therefore rightful home of the artifacts, and so the public educational provision in both countries (museum spaces, school materials, public talks, guidebooks, events, etc.) is skewed toward each country's interpretation.

Another such issue is how publics are educated about or even allowed to shape the relevance of the past to the present. In the case of Greece, excavations or (more seldom) artifacts processed and communicated by archaeology professionals in specific disciplinary ways are taken up and often radically reinterpreted by their publics, creating types of knowledge which directly affect e.g. the site's funding, security, political and social role. This has been the case with the excavation of the site of Amphipolis in Northern Greece. The public education attempts by its archaeologists (in the form of talks, interviews, media releases, high-level site tours, etc.) have fueled a range of public receptions and understandings, almost none of which might have been intended by the experts: the politicization of the site in the Greece-FYROM/North Macedonia debate, its use by ultra-nationalist groups as a banner of Greekness and its (mis)interpretation as a potential burial place for Alexander the Great.

Similarly, in both countries, there have been long-term tensions between the archaeological and religious use of non-Christian monuments, e.g. at Stonehenge (UK) or at the Temple of Olympian Zeus (Athens, Greece). In such cases, the past is made relevant or irrelevant to the present, depending on the site's sociohistorical circumstances. It can be made relevant by agreeing concessions between interpretational disagreements: e.g. the archaeological interpretations of the use of Stonehenge are not necessarily those held by its druids. It can also be made irrelevant by

banning conscious efforts at mutual education: e.g. the archaeologists ignore and condemn neo-pagan worship at the Temple of Olympian Zeus.

Future Directions

The aforementioned examples and discussion raise several questions, which ultimately affect the ways in which we can conceptualize potential future directions of public archaeology education. On the one hand, we would have to survey the desires, goals, and needs of archaeology's stakeholders; on the other hand, we could conceive possible directions which might incur collective benefits.

In order to do this, we first need to ask who owns and can control archaeological knowledge in the case of public archaeology, which, in turn, directly or indirectly funds archaeology as a discipline. An easy answer, especially a few decades ago, would have been "the professionals," perceived to be the experts in what the public (singular) needs. As we have seen in this entry, however, this is no longer a tenable position: there is no such thing as a single public, and the professionals may be aware of (and indeed constrained by) their own methodologies, but they are in need of constant dialogue, especially in this postmodern, pluralistic age. Indeed, a considerable source of tension currently seems to be that the archaeological educational relevance advocated by specialists through official publications, events and outreach (e.g. press releases, site tours) may not necessarily be the relevance desired by publics in *topoi* such as social media, public activities and public debate (e.g. press articles, marches and demonstrations). In addition, is public archaeology and its educational provision always voluntary, or can it also be an involuntary action, and should the latter be regulated? The issue here is really whether the education imparted is distorted or used for different agendas and, consequently, whose standards are being followed (the specialists' or the funding publics'). If we are able to answer these questions, then we will be able to reflect as to the makeup of the body (co) creating educational opportunities, as well as the nature of these opportunities. And if we want to progress public archaeology education in meaningful ways, a more inclusive and interactive synergy is needed, through ethnographic research, consultation, co-curation, etc. (e.g. Bezerra 2005; McGill 2010), without necessarily falling into the trap of relativism or dissolution of archaeological method.

Second, we need to reflect on the goals of public archaeology education. As we have seen above, they can be very varied, depending on how heritage is perceived and legislated, as well as how archaeology and education are practiced around the world. One of the goals is the physical and notional sustainability, stewardship and conservation of archaeological sites and materials. Another is the financial and professional sustainability of the archaeology sector. Yet another is the political instrumentalization of archaeology in the public domain (e.g. in nationalism, activism, etc.). Consequently, is public archaeology education more about manipulated information (i.e. facts and figures) or about pedagogy (i.e. the cultivation of attitudes)?

A number of voices, including this author's, as well as a number of examples discussed above, suggest that the overarching educational desideratum in most cases seems to be how to make the past relevant to the present. There are many ways in which this is currently being implemented, which can be enhanced in the future: outreach, inclusive events, curriculum design, site protection and education about this, new technologies, and reconceptualization of publics and communities (online, cf. Richardson 2013, and offline). Such educational opportunities create local and regional pride, connect people's lives to the past in meaningful ways, build communities, and often change people's worldviews. The latter, I believe, is the most important future direction of public archaeology education. Through informed and collaborative provision (e.g. community service learning, cf. Nassaney 2012, etc.), public archaeology and its pedagogies can truly be forces for social change (cf. Silberman 2007: 190; Little 2012: 405–407). In a world of

social and economic upheaval, "post-truths," and disenfranchisement, an informed and multi-sited archaeological education has the power to provide valuable service. "Archaeological literacy," as Franklin and Moe (2012) put it, can empower us collectively toward critical thinking and historical insights (Batroy 2012: 564), toward an understanding of the human condition, and toward community building, inclusivity and pluralism (social, national, cultural, etc.). It can thus enable us to safeguard our past, comprehend our present, and plan for our future.

Public Archaeology, The Move Towards

Dante Angelo
Departmento de Antropología, Universidad de Tarapacá (UTA), Arica, Chile

Introduction

One of the most evident changes brought by the reflexive turn in archaeology is perhaps the move towards public archaeology. Although in its inception public archaeology was primarily related to educational concerns and efforts to attain public outreach (McGimsey 1972; Stone and Molyneaux 1994; Jameson 1997), in recent years it has become more complex to define. This slipperiness has to do with the fact that, as an umbrella term, public archaeology now encompasses a wide array of concepts and purposes (Schadla-Hall 1999; Merriman 2004a; Matsuda and Okamura 2011). This turn towards public archaeology, thus, can be better characterized by a gradual and explicit involvement of archaeology practitioners in different and intertwined levels of educational, political, governmental, and ethical issues. In this sense, it relates to and involves concepts such as development, heritage, applied archaeology, and community archaeology.

Definition and Historical Background

The term public archaeology attained recognition in the early 1970s with Charles R. McGimsey's publication with this very title (McGimsey 1972). Then, it was mainly meant to address the dangers of destruction of archaeological remains, raise broader awareness about this problem, and support legislative efforts aimed at protecting them (Schadla-Hall 1999). The increasing pressures of development, observed mainly in the United States and European countries, posed a challenge to professionals and state institutions as they were increasingly confronted with the destruction and loss of historical and archaeological heritage. The rise of independent archaeological contractors, as well as the participation of some universities in the development process, provided some means to mitigate such destruction and gave rise to Cultural Resource Management (CRM) or contract archaeology. Known also as heritage management and archaeological resource management, one of the main tenets of CRM archaeology was the preservation of past remains, conceived as a resource belonging to societies (MacManamon and Hatton 2000). The past, henceforth, came to be seen as a public right pertaining to the interests of the whole society (Carman 2002; Merriman 2004b). As observed by Smith (2004: 6), although the equal accessibility and significance to all comers implied by the term "resource" was subsequently challenged, the prolific efforts to develop outreach and educational programs and prevent the destruction of archaeological remains also contributed to make the subject relevant to a broader audience. Additionally, scholars drawing from critical theory emphasized that a reflexive stand oriented to reinforce stakeholder communities' civic and proactive engagements with the past should be paramount to public archaeology (Leone et al. 1995; Little and Shackel 2007).

In any case, the term public archaeology began to take its current shape with the involvement of archaeology in public debates, traversing the borders of traditional academic archaeology, to respond to public interests about the past. The rationalist and political neutrality of scientific discourse, prevalent in the discipline during most of

the 1960s and 1970s, was fiercely challenged in the early half of the 1980s. Theoretically, factions of the post-processual movement in archaeology, strongly influenced by feminist and Indigenous discourses, challenged the authority and ethics of representation of the "other" and echoed the cultural critique about the hegemony of the Western academy (Wylie 1982; Hodder 1986; Pels 1999); most of these critiques called for a more inclusionary archaeological interpretation, in which Indigenous peoples and different local communities and stakeholders could participate (Layton 1989; Hodder et al. 1995). Following the controversies that arose as a result of the creation of the World Archaeology Congress (WAC) in 1986, a much more politicized world emerged for archaeology (Ucko 1987; Shanks 2004).

Authors such as Michael Shanks and Christopher Tilley (1992) and Mark Leone and colleagues (Leone et al. 1987, 1995), for example, emphasized the need for a critical appraisal of the interrelationship between archaeology and politics and to understand the power relations established discursively through historical and archaeological knowledge (see also McGuire 2008). Advocating for an inclusion of the different emerging voices, then, these contributions set an interpretive movement that came to call into question the prevalent authority over the past held by the discipline. With the advent of politics of identity and recognition, the past became a realm of contestation in which a variety of contemporary interests became interweaved. Thus, steering public archaeology in new directions, the reflexive turn established by an overt critique to objectivity, rationalism, and scientific archaeology coalesced with the politics of cultural recognition and provided the basis for a more inclusive debate, raising issues and categories such as identity, ethnicity, and so forth.

Key Issues/Current Debates

The move towards public archaeology has brought a new array of themes and topics to the discussion about archaeological practice and theoretical consideration. Prominent in the current debate related to this recent turn in the archaeological inquiry are the discussions about transnationalism, tourism, sustainable development, commodification of cultural resources, and global–local relationships (Smith 2006). The impact that this reflexive trend had on archaeological practice can be scrutinized at least in two interrelated aspects: collaboration and heritage. On the one hand, emanating from various angles, critiques to academic authority pushed archaeologists to reconsider their position as the only stewards of the past and prompted them to engage in collaborative programs with a wide array of Indigenous and local communities (Faulkner 2000; Colwell-Chanthaphonh and Ferguson 2010; Gnecco and Ayala 2011). Thus, a more nuanced perspective about public archaeology, although still involving educational and legislative aspects, now incorporates ethical concerns and acknowledges that the practice of "scientific archaeology" can no longer be the only authoritative voice about the past. Moreover, in investigating the past, archaeologists need to be aware about social, "racial," political, and other tensions emerging from dissonant interpretations of the past; the practice of public archaeology, therefore, also incorporates components of ethics and socio-political accountability.

On the other hand, although still concerned about protecting the past, public archaeology now actively engages in issues related to the management of sites through a nuanced understanding of cultural and archaeological heritage. Heritage, as a concept, has recently made its way to the core of archaeological theory. Closely related to the politics of recognition mentioned above, the concept of heritage has recently opened a new and vigorous debate, expanding the considerations of what constitutes the public and, therefore, what public archaeology or archaeological practice should entail. The involvement of different communities of stakeholders that stepped forward to express interests or concerns about archaeological sites and archaeological discourse constituted a new challenge for the discipline (Russell 2006; Smith 2006). Barbara Bender's (1998) seminal work about the emblematic archaeological site of Stonehenge provides an exemplary approach to

the analysis of the historically dynamic contexts that stakeholders (including archaeologists) can become involved in. Eluding the essentialist thought that commonly portrays Indigenous peoples and descendant communities as the only "other voices" that come forward to question archaeology, Bender's work also reflects on the formation of new groups of stakeholders and the politics that surround them. By the same token, critical awareness about the decisions, interpretation, and management of cultural and archaeological heritage acquired global connotations through the increasing myriad of stakeholders as well as a burgeoning tourist industry related to the consumption of the past.

This global trend of cultural consumption closely relates to a process of shrinking of distances which – fueled by a burgeoning and constant flux of peoples, goods, information, and capital – consolidated globalization as a phenomenon with a wide array of economic, cultural, and political implications worldwide. For many, globalization meant the standardization of culture as well as economics, with the consequent establishment of a single dominant and global cultural order; however, contradicting the fears of homogenization predicted as part of the effects of globalization, the blooming of cultural diversity set under the auspices of multiculturalism amounted to define tourism as one of the key themes in archaeological theory (Merriman 2002; Meskell 2005). Consequently, archaeologists have started to turn their attention to the relationship of the discipline with the heritage and tourism industries. Related to this current trend, tourism and cultural recreation have become central to archaeologists as the public increasingly demands the articulation of new narratives about the past (Holtorf 2005).

As heritage or cultural tourism consolidates as one of the most important global industries (Urry 2002), the interest in archaeological heritage has gradually increased over the last few decades. With a burgeoning demand of cultural consumption fostered by an exponentially increasing flux of capital and peoples, tourism promoted archaeological heritage to new dimensions. Additionally, the gradual involvement of different stakeholders and local communities in heritage issues brought up several concerns regarding property and propriety of heritage. Archaeologists, in this sense, have been pushed to explore ever more complex and intertwined relationships involving individuals, communities, states, and global agencies at different scales. Local understandings of heritage values, however, as demonstrated by different scholars, can differ significantly from those parameters conceived as universal. The past, once aptly depicted as a "foreign country" (Lowenthal 2003), became the arena in which active – and sometimes dissonant – social constructions continuously take place through heritage and tourism and, therefore, have opened new lines of debate regarding its ownership and stewardship (Smith 2006).

International Perspectives

Arguably, then, heritage tourism has become one of the most profitable industries of recent decades and a global force that increasingly extends its branches throughout the world (Hoffman et al. 2002; Higueras 2008). As part of this global trend in which archaeological heritage is now involved, the heritage industry included in the core of developmental policies of global organizations such as the World Bank has been endowed a reputation of being a determinant factor for economic growth, especially for developing countries (Meskell 2005; Lafrenz 2008). Whereas it is often argued that heritage can play a significant role in overcoming economic adversities, less is said about its detrimental effects on local communities. While some argue for the necessity of making useable pasts, as something that can be assessed to provide economic profitability, others question the beneficiaries of these profits (Lafrenz 2009). As the expectations of tourism and heritage industries have risen, the attempts to attain the inscription of sites in the prestigious World Heritage Site list by different country parties have also escalated. A large percentage of recent nominations, related to the aforementioned search for economic growth, have to do with the fact that the attempt to gain such a reputable designation

will help to promote heritage sites as marketable tourist sites.

In this sense, with an exponential number of new local sites and museums that now compete to attain some recognition while others focus on maintaining their high profiles and well-preserved statuses, the values and principles for such recognitions and other tenets heralded by global organizations are being called into question. Questioning the set of values that have commonly been used to define cultural and archaeological heritage, some archaeologists now actively work to emphasize local views and values regarding the past (Faulkner 2000). Challenging previous top-down perspectives that were mainly concerned with a rather monumental and conservationist view of archaeological heritage, the intervention of new stakeholders established the need for archaeologists to understand the emergence of new relationships between local interests and global demands (Hodder 2003). Whereas international agencies and organizations such as UNESCO, ICOMOS, and WHC had advanced important contributions to deal with issues deeply affecting cultural heritage, such as looting and trafficking of archaeological remains, a new approach to heritage also emphasizes ethical concerns pertaining to cultural property and human rights (Brodie et al. 2000; Brodie and Walker 2002; Silverman and Fairchild Ruggles 2007).

In this scenario, as heritage has become the axis where these contemporary social understandings and active constructions of the past come together, public archaeology confronts a wide array of challenges in its efforts to engage with different communities and stakeholders. Related to this, by drawing away from conservative approaches to heritage, public archaeology has also highlighted the importance of including different criteria and considerations, other than those defined by the World Heritage Convention in the definition of valuable heritage sites (Cleere 1996; Lafrenz 2008). As a result, heritage organizations and state agencies have been compelled to take into consideration a more dynamic and diversified understanding in which cultural and heritage value could be also related to political restitution or economic leverage and well-being. Nonetheless, although different countries have adopted the globally sponsored efforts towards the recognition of their Indigenous peoples, for many of these populations, to attain such recognition implies a compliance with guidelines of authenticity in order for them to prove cultural and genealogical continuity so that they may be conferred with the rights to cultural ancestry (Clifford 1988; Hale 1999).

Thus, some of the questions still to be addressed regarding the intersection of public archaeology and tourism are related to the new power relationships and cultural dynamics provoked by the commodification of cultural heritage. For instance, the demand for authentic experiences related to this global trend of cultural consumption has commonly driven heritage managers, cultural planners, and tourism-related policy makers to resort to the use of archaeological discourse to recast "authentic" – or rather essentialist – views of culture (Castañeda 1996; Benavides 2004; Hamilakis 2008). This is particularly the case for Indigenous peoples and other historically marginalized communities that, related to their cultural and political struggle, opt or are compelled to resort to heritage and cultural tourism as strategies to boost their economies (Meskell 2005; Lafrenz 2008); in this sense, Indigenous peoples remain commonly represented as passively reproducing a colonial imaginary in the realm of heritage. Furthermore, it has been generally the case that most of the countries whose archaeological heritage is administrated by state and centralized agencies not only tend to emphasize its economic importance for local development, as part of their policies, but also – and primarily – to reify it as the legitimate roots of nationhood (Rowan & Baram 2004; Hamilakis 2008). Therefore, despite the fact that these strategies have prompted a successful public recognition of multiple ethnic groups, which is one of the reasons why they became widely adopted as part of different state policies, they also exert powerful constrains and fixities determined by the very demands posed by consumption.

Different collaborative projects between local communities and archaeologists have, therefore,

been caught up in a series of paradoxes. On the one hand, collaborative projects struggle to protect archaeological sites and to confront the destructive threats of development and sometimes, ironically, even harmful effects of tourism; as it was noted, "cultural tourism can pose a significant challenge to the management of heritage sites, as visitors can have positive and negative impacts, and increased visitation means increased responsibility, especially in terms of on-site safety" (Smith & Burke 2007: 239). On the other hand, public archaeology projects that involve working with economically disadvantaged communities often involve efforts relating to political empowerment and identity issues as well as attempting to orient their efforts to promote heritage tourism opportunities as part of these communities' social and economic sustainability. In that sense, the move towards public archaeology needs to be understood as an ongoing process in which the practice of archaeology itself becomes reconfigured. It comes as no surprise that public archaeology, as part of its response to these new challenges, has adopted and stressed the importance of a rather involved take on the politics surrounding the conceptualization of the audiences towards whom our work is directed, which – at its turn – implies a strong reflexive slant towards ethics.

Future Directions

The objectives of public archaeology largely remain framed within the original goals, namely, committed to reaching broader and more diverse audience whose needs and demands regarding the past can be advanced and supported by the work of archaeologists. As part of this, public archaeology is still concerned with the protection and preservation of archaeological heritage and seeks to provide adequate management plans to respond to tourism global needs, for instance, while keeping the balance between tourism expectations and the carrying capacity of archaeological sites. Nonetheless, public archaeology is also becoming increasingly involved in collaborative efforts to yield more inclusive considerations of local perceptions of the past, as part of the categorization of archaeological sites as global tourist destinations. Practitioners involved in public archaeology are also aware that such categorization cannot be fulfilled by any standardized set of practices nor unique codes or universal paradigms. Arguably, the present times are characterized by highly politicized contexts in which claims to heritage and identity, however controversial, are part of a struggle for power and still rely very heavily on discourses about the past. Regardless of the aforementioned paradoxes, or perhaps precisely because of them, public archaeology is gradually moving to include developers and tourist operators, as well as state agencies, educational partners, and legislators as part of the equation (Hoffman et al. 2002: 31). Therefore, it can be said that what public archaeology now faces is an urgent need to reconsider previous notions of what has been understood by "the public," in order to achieve even wider conceptualizations.

In this sense, if one contends that public archaeology is mainly meant to take care of the public interest in the past, then it will also be necessary to acknowledge the impossibility of considering a general, single, and homogeneous public (McGuire 2008: 86–7). It follows from here that archaeologists need to keep considering who this public is – or rather, who the different audiences we are addressing and responding to are – and the ways in which it/they become constituted, as well as to recognize the effects, influences, and contentions fostered by a burgeoning process of globalization upon the public's interests in the past. It is crucial, therefore, to take into account the power relationships displayed between micro and macro levels (stakeholder communities, state agencies, and global organizations or corporations) and the way national or global entities' decisions and actions equally impact archaeological resources and upon the different audiences' criteria of value and importance of the past. In order to advance its goals and attain a fully fledged engagement of archaeology with the different stakeholders and constituencies interested in the past, it will be necessary to weave all those parameters into some of the common

themes that have, thus far, characterized public archaeology. Then, any education outreach projects oriented to the valuing of the past (and its preservation), as well as any attempt to use archaeology as an effective way to overcome economic imbalances or prompt political action by lobbying for recognition of previously disenfranchised communities, will need to make sense of the conditions and differences in which these activities are going to be carried out as part of this engagement.

Public Education and Archaeology: Disciplining Through Education

Emma Waterton[1] and Hayley Saul[2]
[1]Institute for Culture and Society, Western Sydney University, Penrith, NSW, Australia
[2]Institute for Culture and Society, Western Sydney University, Parramatta, NSW, Australia

Introduction

In 1994, Brian Molyneaux suggested that one of the most obvious, yet critical, functions of archaeology for society was education (Molyneaux 1994: 3; see also Stone 2004; Willcock 2004). Since then, the pairing of archaeology with education has gained considerable ground; so much so that while the term "public education" may not necessarily come to mind for all scholars and practitioners working within the field, most will hold an implicit familiarity with its central tenets via their connections to outreach, community archaeology, social inclusion, or public participation. This is because all of these concepts – and the practices they reflect – emerged out of a broader social movement that prompted archaeologists to start thinking about, reflecting upon, and dealing with the complex relationships between "the

discipline" and "the public." As with other attempts to engender public participation and support, education operates as a powerful point of connection between scholars, practitioners, politicians, and a vast variety of stakeholders and interest groups. A useful consequence of this arrangement has been the burgeoning of a range of learning tools, public presentations, "archaeology weeks," festivals, and volunteering opportunities. Yet despite the proactive language often used to describe this area of development, it is important to remember that it can play out in a number of ways, not all of which are positive.

Definition

Archaeology can tell people a great deal not only about human experiences in the past but in the present, too (Henson 2011). It is, by its very nature, educative. Despite this, not a great deal of critical attention has been channeled towards archaeological education as a subject of enquiry in and of itself – with the exception of sustained work by Don Henson, John H. Jameson, Peter Stone, and, more recently, Yannis Hamilakis. What, then, is implied by the heading "Archaeology within Public Education?" To be clear, in this context, the term "public education" does not refer in any way to the classification of a school as it might in the UK, the USA, or Australia. Rather, it refers to the intersection of a broad spectrum of educative activity with the general public. The term "education" can loosely be described as a process of producing and disseminating knowledge. More sharply defined, it denotes a number of different types of learning, beginning with compulsory schooling, vocational learning, and further education, all of which are captured by the category *formal education* and take place within schools, colleges, and universities. To this can be added *extra-formal learning*, which refers to those who opt to extend their knowledge by participating in less formal classes and courses offered by learning institutions. In the UK alone, Don Henson (2011: 219) estimates that there are somewhere in the region of 15,000 people enrolled in these sorts of formal or extra-formal archaeology courses.

Despite these numbers, the forms of learning most commonly associated with the term "public education" in archaeology are those that fall into the categories of *informal learning*, *non-vocational learning*, and *lifelong learning*, which are united in their association with a "practical knowledge tradition which stresses direct experience" (Livingstone 2001: 3). This is the nub of archaeology within public education. Although the most stereotypical example undoubtedly remains the on-site excavation, these categories of learning produce a plethora of educative experiences, including guided walks, school visits, live interpretation, outreach, storytelling, landscape assessments, artifact handling, work placements, popular publications, programs designed to accommodate public participation, public presentations, heritage open days, fairs, historical societies, and collaborative projects. Recent additions to the fold are things like museum displays and their interpretation, which have come to be envisaged as powerful learning tools in recent museology literature. Less likely to spring to mind when one thinks about public education are self-directed activities such as volunteering; though not obvious, these sorts of activities are nonetheless important learning experiences within the field. Brenner (2016: 6), for example, recognizes experiential pedagogic practices to be an area where around 70% of effective learning is done, compared to only 30% in classroom or mentor-based education. Like formal education, at the core of these activities is the production and dissemination of knowledge.

There is, however, a second, more muted, aspect to education – both formal and informal – that must also be accommodated within its definition; that is, knowledge, once produced and disseminated, goes on to perform particular social, cultural, political, religious, or economic roles in wider social life, based upon how it fits with different identities and their respective access to power and resources. Education, whether public or otherwise, is thus also political. Whether one is referencing high school curricula or a program of lifelong learning, it is always possible to peel away the initial layers concerned with course outlines, content, timetabling, assessment, or delivery and glimpse the deeper ideological currents.

Indeed, as Yannis Hamilakis (2004: 295) points out, choices are made, and those choices say something about issues of power, value, and assumption, all of which in turn are revelatory of a society's underlying social structures and the political persuasions of the day. These sorts of arguments are applicable not only in countries where a form of repressive government might already be anticipated but in progressive and democratic countries, too. In the UK, for example, archaeological- and heritage-based public education outlets may have embedded within them assimilatory messages that align with either New Labour's agenda of social inclusion or the more recent Conservative government's attempts to foster national cohesion, both of which are implicitly fuelled by a fear of difference (Waterton 2010). In this scenario, particular narratives of the past, along with their associated cultural symbols, may be foregrounded in museum displays or other interpretative devices because of their ability to facilitate national identity formation and thus support a certain kind of citizenship. At the same time, other educational institutions may bend the same narratives in such a way as to inspire emancipatory thinking. Either way, the point here is that public education cannot simply be accepted as universal, stable, or, indeed, always necessarily "good" (Lewis 2009).

Historical Background

Countries such as the UK and the United States have a relatively long history of promoting archaeology within public education, a point best explained by the arrival of an ethically engaged program of stewardship in both countries in the 1960s and 1970s, which is today associated with the terms "archaeological heritage management" in the UK and "cultural resource management" in the USA. An important and lasting consequence of this has been the conceptual and theoretical shift felt within the archaeological discipline, which led to a questioning of the legitimacy of its assumed claims to knowledge and control over the past. This, along with the growing intensity of market-driven policies and tropes of accountability, triggered an increase in the acknowledgment of the public's right to be consulted and involved.

In the USA, where archaeology is strongly influenced by anthropological traditions, the relationship between the two was cemented at the governmental level, with the US National Park Service, the US Bureau of Land Management, the US Department of the Interior, and the US Army Corp, for example, all implementing programs or projects aimed at developing public involvement in archaeological activity. A useful example of one such project is that of *Project Archaeology*, a collaboration of the US Department of the Interior, Bureau of Land Management and Montana State University, which is an education program for "everyone interested in learning or teaching about our nation's rich cultural legacy and protecting it for future generations to learn from and enjoy" (*Project Archaeology* website). A focus upon archaeology's educative capacity developed in the 1970s and, as Laurajane Smith (2004: 90) points out, can be attributed to a number of concerns. First and foremost, however, American archaeologists at that time were troubled by the public image of archaeology and sought to redefine the discipline (Smith 2004). From early on in the USA, public archaeology has manifested a reflexive and self-aware ethics towards Indigenous rights and the capacity of education to empower (Richardson and Almansa-Sánchez 2015). From this emerged an emphasis on notions of "common" heritage and public "good," to which archaeological scholars responded by highlighting the discipline's need for a duty of care and responsibility towards a range of publics. As Matsuda and Okamura (2011: 2) have pointed out, this impetus was heavily influenced by debates between processual and postprocessual thinking in North American archaeological circles at the time.

The Council for British Archaeology, founded in 1944 with the slogan "archaeology for all," is a prime example of historical agitation for archaeological education at the institutional level in the

UK, evidenced particularly by the establishment of the Young Archaeologists' Club in 1973 (Henson 2011: 220). Since then, a range of reports and policy documents have emerged that foreground education within the sector, including *A Common Wealth: Museums in the Learning Age* (1997) and *Opening Doors: Learning in the Historic Environment* (2004). It is important to acknowledge the political climate that continues to surround such developments in the UK, particularly the influence of the New Labour government (1997–2010) and their policy platform of social inclusion. Here, the turn to ideals of public value, issues of access, and a democratization of learning had a powerful effect on the way archaeology was conceptualized at the governmental level, evidenced in part by conferences such as *Heritage for All* and *Capturing the Public Value of the Past* and in policy position papers such as *The Historic Environment: A Force for Our Future*. In turn, these policies, specific to archaeology, heritage, museums, or the historic environment, can be traced to a broader impulse within the UK towards learning, as captured by documents such as *Learning Works: Widening Participation in Further Education* (1997), *Further Education in the New Millennium* (1998), and *Learning for the 21st Century* (1997).

At the more global level, a historical injunction towards public education can be traced through a number of policies and publications. The European Convention on the Protection of the Archaeological Heritage (Valetta Convention), revised in 1999, is a case in point, as illustrated by Article 9, "Promotion of Public Awareness," which explicitly references education and public opinion. Likewise, the Ename Charter of 2002 highlights the importance of interpretation at cultural heritage sites as an educational resource. Finally, a third example can be drawn from the more recent European Landscape Convention (2004), widely referenced by archaeologists and heritage scholars working across Europe, which prioritizes education and public awareness in Chap. II, Article 6 of the Convention. All three can be intertextually linked to broader European Union initiatives, such as the Lifelong Learning Programme: Education and Training Opportunities for All, established in 1997 by the European Commission, and the Strategic Framework for European Cooperation in Education and Training 2020, developed in 2009. Finally, it is worth noting that the World Heritage Centre also operates an educative strand, which includes the international network, Forum UNESCO: Universities and Heritage, and the World Heritage Education Programme, launched in 1994 (for further information on the World Heritage Education Programme, please visit http://whc.unesco.org/en/wheducation/). These have culminated more broadly in a 2015 priority area for the United Nations International Commission on Financing Global Education Opportunity, which seeks to widen participation for the "Learning Generation" in order to reduce the skills gap between low-income and high-income countries around the world.

Key Issues/Current Debates

Although many of the debates and issues observed within the arena of public education have much in common with those that surround "community archaeology," "ethics," and the "politics of display," they are worth reiterating here as education is one of the most public and – importantly – authoritative domains through which archaeological knowledge is communicated (Hamilakis 2004: 296). A key reason for its prevalence in these debates is that "education" is often argued to be a vital avenue through which particular messages about the past are passed onto the public, thus touching upon topics of power, control, and authority (see Smith and Waterton 2009; Waterton 2010). A number of commentators have created models that capture the way education figures within the wider remit of archaeology, such as Nick Merriman and Cornelius Holtorf, though it should be noted that their explanations are aimed at public archaeology more generally. For example, Merriman (2004) introduces the

"deficit model" and the "multiple perspectives model," with public education playing a significant role in the former by virtue of its ability to *inform*. The "deficit model" foregrounds the role of the expert in encouraging public understanding of a scientifically endorsed past, while the "multiple perspectives model" recognizes that public experiences of their past should guide the archaeologist to augment the stimulation and enrichment that heritage already offers the public. This roughly accords with Holtorf's (2007) "education model" and "public relations model," both of which similarly rest upon a unidirectional flow of information from archaeologist to public. Quite distinct from these essentially closed processes are Merriman's "multiple perspective model" and Holtorf's "democratic model," both of which open up the dialogical relations such that communication – between archaeologists and the public – becomes two way. As Matsuda and Okamura (2011: 13) have recently argued,[f]rom this viewpoint, archaeological education does not differ much from engagement with different pasts, in that both approaches need and encourage dialogues between archaeologists and members of the public.

That said, there is still a tendency to assume an educational stance that veers closer to the "deficit model" or "public relations model" within the archaeological discipline. Certainly this is the case at the policy level, although these days there are an impressive array of case studies that can be drawn upon to suggest otherwise, some of which are detailed below. Those case studies aside, it can be argued that at the broader level, individuals and groups that stand outside of the discipline are rarely given a role in defining messages about the past; rather, they are seen as recipients of said information. Public education, in this guise, becomes something that is done *for* the public instead of something that is done *with* them. Holtorf, building upon an argument originally posited by John Cole in 1980, remarks that this sort of approach to teaching people about the past becomes little more than a branding exercise, through which the fostering of a belief in the necessity of its preservation in turn fosters a belief in the necessity of the discipline itself (Holtorf 2007: 155; see also Simpson 2009). Nowhere has this been more powerfully argued than in Denis Byrne's article *Buddhist Stupa and Thai Social Practice*, in which he states:

[t]he call for public education has been a recurrent theme in the literature of archaeological heritage management (Byrne 1991), where both Western and non-Western archaeologists see it as an antidote to 'indifference' and 'apathy' towards the fate of archaeological sites. Posited here, implicitly, is an infantile condition: prior to education a void exists in the public's mind where knowledge of and respect for the material past should be (Byrne 1995: 278).

As Byrne (1995: 278) goes on to argue, "multiple and mature discourses on the material past already exist in the space archaeology depicts as a void. What archaeology intends, really, is not education but re-education."

Current debates about public education in archaeology are thus inclined to push for the development of alternative ways of thinking about this relationship. Here, in particular, overlaps between education debates and those occurring in broader public archaeology debates can be seen. Like Holtorf's (2007) "democratic model," for these debates the trick lies with changing the channels of communication and inserting the notion of "politics" into the equation. As Matsuda and Okamura (2011: 10) point out, the process becomes less about moving clusters of information from one domain into the next and more about appreciating that the past is understood – and *used* – differently by different social groups. What this means in practice is that there can never be one single education model and certainly not one that attempts to impose ideas onto the public. Indeed, in some scenarios, social groups will seek out archaeological education because understanding the past is central to a larger social justice claim. Here, the role of education would be a collaborative one, geared towards facilitating social, cultural, or political recognition and, perhaps, access to particular social or political resources. In other scenarios, social groups may be seeking a relaxing day out, a pleasurable experience far removed from those struggles for identity that often characterize social justice claims.

Here, the role of education may well be an instructive one, which brings with it an increased awareness of a particular aspect of the past. Either way, the role of education is a powerful one, and the archaeological discipline must remain mindful and respectful of that.

International Perspectives

Despite the above concerns, a number of useful and positive examples from the United Kingdom and Europe can be showcased here. A wealth of archaeological digs and training programs are offered across Europe (e.g., in Spain, Greece, Italy, Macedonia, Portugal, Cyprus, and the Netherlands), many of which encourage participation from not only those enrolled in formal education but also those engaged in practices of informal and self-directed learning. Biskupin, an Iron-Age reconstruction site in Poland, is a good example of the utilization of archaeology for public education. The archaeological museum associated with the site offers a range of lessons and experimental opportunities for interested parties and organized school visits, as well as both smaller- and large-scale festivals. In Norway, a process of informal education is undertaken by participants associated with local history societies, who develop and maintain signposted cultural landscape trails that detail archaeological features (Jones 2007). These same societies are also involved in the formulation of local history walks, such as the Heimdal Local History Society in Trondheim, which arranges an annual walk that showcases the memories and experiences of older and long-established residents in the area (Jones 2007). A particularly fascinating example of the educative benefits of archaeology are highlighted by *Operation Nightingale*, a military initiative coordinated by the *Defence Archaeology Group* (DAG) to aid in the rehabilitation of injured service-people. This initiative has conducted a number of projects, including the Barrow Clump project and the Marne Barracks excavation (see Sherlock 2017). While the communality of archaeological fieldwork is one important way to reduce isolation, Winterton (2014) reflects that learning the meticulous practice of excavation also brings therapeutic benefits, supports aspiration, and resituates curiosity in activities that complemented a military skillset.

A range of government institutions have a vested interest in the issue of public education in the UK, too, such as the Department for Culture, Media and Sport, the Department for Education and Skills, the Commission for Architecture and the Built Environment, the National Trust, English Heritage, the Portable Antiquities Scheme, and the Council for British Archaeology. In the UK context, it is possible to see clearly the interrelations between broader social policy and archaeology, particularly if one looks at the influence of the various permeations of policies aimed at alleviating disadvantage, such as the Educational Priorities Areas instigated in the UK in the 1960s, which can be glimpsed in the more recent policies of social exclusion (Smith et al. 2007). These were a form of "positive discrimination" aimed at prioritizing areas characterized by economic depression and associated issues of social exclusion. An area targeted by this and similar policies is Moston in Greater Manchester, an outcome of which has been the "I Dig Moston" archaeology project, which began in July 2005 and is now often referred to as "Dig Manchester." This runs in conjunction with the University of Manchester and Manchester Museum and was initially initiated by a local archaeological and local history group. It is supported by the Heritage Lottery Fund and the Manchester City Council. In terms of public education, this initiative extends to school groups, community groups, and the general public and includes archaeological training in excavation techniques, finds analysis, geophysical survey, family history, and heritage trails (for further information on the Dig Manchester project, please visit http://www.digmanchester.org.uk/). More than this, the project aims at tackling deeper structural politics and realizing positive change. More recently, the Shoreditch Park community archaeology excavation, funded by the Big Lottery Funds' "Their Past Your Future" program and managed by the Museums, Libraries and Archives Council, the Hackney Council, and Shoreditech Trust, provided opportunities for lifelong learners

and schools to engage with WWII, local history, and the practices of archaeology (Simpson and Williams 2008).

In wider, non-Anglophone regions, archaeology and public education debates have often been entangled in the politics of postcolonialism and Indigenous self-determination, development, and heritage tourism. In Afghanistan, for instance, the National Museum in Kabul is playing an educational role in public diplomacy, with an awareness among practitioners that culture and history are indispensable in moving towards social and political unification and the formation of a peaceful identity (Remsen and Tedesco 2015). Here, education through the museum must carefully plot a course between building a national identity and representing volatile and politically diverse identities. The museum exhibition is also a forum for health education, as illustrated by the example of participatory exhibition development in Malawi, a country where the effectiveness of hospital attendance suffers from negative public perceptions. McKew (2015) worked with local communities near the Queen Elizabeth Hospital in Blantyre (Malawi) during workshops to assess the needs and perceptions of the hospital environment and to share their knowledge and interests around themes such as blood, diseases, drugs, vaccines, and DNA. A hands-on, interactive exhibition was designed around seven questions that participants had asked, such as how a vaccination works and malaria facts. In this instance, such collaborative educational exercises witnessed an improvement in perceptions about the approachability of hospitals for participants. But beyond development, museums have also become sites of cross-cultural reconciliation, spurred by critical postcolonial aims. An excellent example is the Museum of Kapuas Raya in Indonesia, which Van Hout (2015) describes as having an "in-betweenness" to its exhibition which emerges as a kind of hybrid, a careful conversation between Indonesia's colonial past with the Netherlands and its contemporary identity politics. What this means, therefore, is that the educational capacities of the museum, as it explores this postcolonial dialogue, are inherently dynamic.

Future Directions

Although research and commentary papers on the role of education in archaeology have started to emerge, there still remains a dearth of literature that critically and specifically engages with this topic. This is particularly the case outside the Anglophone sphere of Europe, Australia, and the United States (Almansa-Sánchez 2015). Not only are the formal institutions that offer archaeology education ripe for inspection but so too are the ways in which the discipline is spliced together with the public. Never has this been clearer than in today's rapidly changing social and political climate. Add to this the new roles played by the Internet and other technologies such as interactive multimedia, video, animation, virtual reality, simulations, and computer-mediated communication – what opens up is thriving intellectual space for innovative, challenging, and sustained dialogue about the place and shape of archaeology within public education.

Public Humanities and Cultural Heritage

Steven Lubar
John Nicholas Brown Center for Public Humanities and Cultural Heritage, Brown University, Providence, RI, USA

P

Brief Definition of the Topic

Public humanists – public historians, oral historians, folklorists, curators and museum educators, public art administrators, cultural media producers, and cultural policy planners, as well as cultural heritage workers – encourage the public's participation in the creation of meaning about history, art, and culture. They do this in many ways: sometimes as mediators between the academy and the public, interpreting the work of scholars for the public, sometimes as facilitators of public engagement with culture, and sometimes

producing cultural work on behalf of communities. Public humanists work with academic humanists, communities, community cultural organizations, and individuals to explore, preserve, understand, and make use of cultural heritage, values, beliefs, knowledge, and traditions, promoting a shared examination of culture, art, and history to encourage civic engagement.

Public humanists, like workers in the cognate fields of public anthropology and public sociology, strike a balance between serving as translators for the work of academic humanists, on the one hand, and as the spokespeople for the cultural work of communities, on the other. The work of translation (or serving as public intellectuals themselves) represents a traditional approach to the field. Serving as spokespeople for communities, or in Gramsci's term, as organic intellectuals, represents the other end of the spectrum. Most public humanists position themselves somewhere in between these extremes, preferring words like "engagement" to describe their interaction with the public. They provide ways to connect academic and public knowledge, thus creating new understandings.

Public humanities provides a theoretical framework for work in cultural heritage and an expertise useful for balancing and merging academic, community, and personal cultures. Its focus on community serves to put the work of cultural heritage into a larger context by framing heritage as part of the ongoing, contested, creation of meaning about the past and about contemporary culture. It connects cultural heritage to the lives and memories of community members and to community institutions, as well as to academic work. It can open up discussion of community, too often taken as given in cultural heritage work, by asking questions about the nature of community and the relationship of community and culture.

Public humanities can also provide a broader understanding of culture, allowing for greater integration of intangible and tangible cultural heritage with current concerns by subsuming heritage under the heading of community cultural production. Its focus on public engagement and on sharing authority with communities grounds cultural heritage work in cultural policy and ongoing cultural production. And its insistence on the role of community institutions encourages community building that creates longer-term sustainability for cultural heritage work.

Public Involvement in the Preservation and Conservation of Archaeology

Elizabeth Anderson Comer
EAC/Archaeology, Inc., Baltimore, MD, USA

Introduction

In the 1970s and 1980s, archaeology began to enlist the knowledge and interest of the public. Today, community participation in archaeological activities and engaging the interest of the public is widely seen as a necessary and useful way to enhance preservation and protection of historical resources and to generate enduring public support for archaeology. Involvement of the non-professional public as participants and volunteers in background and archival research, survey, and excavation and as oral history/local knowledge

informants, spokespersons, and youth and school program facilitators is widespread, and there is an understanding in the discipline that the goals of public involvement in archaeology can be guided to the best effect by professional archaeologists.

Since archaeological resources cannot by their nature "belong" to a living person and because most projects are supported by public funds, archaeologists have a duty to make discoveries available to the public in museums and other venues such as on-site tours, television, newspaper and magazine articles, movies, blogs, and websites, as well as actively engaging the public in hands-on activities when possible.

Definition

Public archaeology is archaeology undertaken with, for, and, or about the general populace. A. Matsuda and K. Okamura aptly define public archaeology as a "subject that examines the relationship between archaeology and the public, and then seeks to improve it" (2011: 4). Within the ever-expanding definition of public archaeology, there are many subfields: archaeological investigations undertaken for the public, archaeological investigations undertaken with the support of the public, archaeological policies, public education and archaeology, politics and archaeology, archaeology and the antiquity market, ethnicity and archaeology, public involvement in archaeology, archaeology and the law, the economics of archaeology, and cultural/heritage tourism and archaeology (Merriman 2004: inside cover). Involving the public(s) in all aspects of the archaeological process enriches the archaeological study and the public(s). It is thus a reflexive process and one that ultimately can make archaeology more relevant to the public.

Key Issues/Current Debates/Future Directions/Examples

The Global Emergence of Public Archaeology

In the United States, the *Antiquities Act of 1906* ensured that archaeological materials on lands under the stewardship of the federal government would provide public benefit by requiring that all artifacts located on public land be donated to a museum. *The National Historic Preservation Act of 1966 (NHPA)*, the *National Environmental Policy Act of 1969 (NEPA)*, and the *Native American Grave Protection and Repatriation Act (NAGRPA)* each contain a legal requirement for public involvement. Prior to the 1970s, however, archaeologists themselves generally avoided public involvement in excavation and interpretation. In 1972, Charles McGimsey coined the term "public archaeology" stating that there is no such thing as "private archaeology" (1972: 5). Beginning in 1975, the city of Alexandria, Virginia became the first US municipality to establish a city archaeology program, and in 1977 Pamela Cressey became city archaeologist. Alexandria archaeology has from its early days included the public in all aspects of excavation and interpretation including public participation through volunteer work, education in the museum, and outreach activities (Cressey 2005: 22).

In 1981, University of Maryland archaeologist Mark Leone began Archaeology in Annapolis, a public archaeology program and field school which incorporated public archaeology training into the traditional field school format for the first time. Field school students were taught to give tours and interpret findings to the public as a routine part of their training (Leone and Potter 1984).

In 1983, Baltimore Mayor William Donald Schaefer, realizing that archaeology could be used as a powerful tool to bring tourists to a struggling city neighborhood, utilized archaeology as community political activism for the first time. The author, a city archaeologist, hired a theater director to teach crewmembers how to script and present tours to the public. Volunteers of all ages were welcomed and trained to excavate as well as participate in all aspects of the investigation. Press events including in-flight magazine articles, almost daily newspaper articles and television news coverage, a daily radio show, and a front page article in the *Wall Street Journal* (Lubin 1985) brought public archaeology to a heretofore unknown level of exposure and spawned similar

programs across the country (Comer 1998: 12). Thirty years later public involvement in the archaeological process is considered essential. By the fourth quarter of the twentieth century, countries such as Britain, Canada, and Australia were following a parallel course, adding their own innovations. In 1993, Britain's Channel 4 began airing *Time Team*, a weekly series following a team of archaeologists digging a different site each week. The series attracted a large and passionate audience in the UK and overseas. In Australia, the movement toward greater public involvement in archaeology moved to the forefront of archaeological issues (MacKay and Karskens 1999: 110).

As one might expect, "public archaeology has developed neither uniformly nor equally in every country" (Matsuda and Okamura 2011: 7). Around the world, archaeologists are linking what had been a purely academic field to the fascination that the general public has with the past. In some countries, archaeology has become well integrated with the general education provided to students. For example, in Japan, the public, and especially school students, enthusiastically participate in activities at on-site visitors centers, which include opportunities for students to make a replicas of artifacts and contribute to the interpretative process.

Archaeologists throughout the world are innovating, devising and testing methods to involve the public. Public archaeology is thus "a commitment made by archaeologists to making archaeology more relevant to contemporary society" (Matsuda and Okamura 2011: 4). Public archaeology provides a unique opportunity for non-archaeologists to connect with the past. Successful public archaeology programs have demonstrated broad appeal in various age groups and ethnicities (Cressey 2005; Leone and Potter 1984; Comer 1998). It is clear that public archaeology programs can develop local, regional, national, and international constituencies for archaeology and deepen an understanding of the need to protect archaeological sites through conservation and preservation.

"Public" and Archaeology

Xurxo Ayán-Vila and Alfredo González-Ruibal
Institute of Heritage Sciences (Incipit), Spanish National Research Council (CSIC), Santiago de Compostela, Spain

Introduction and Definition

Construction works appeal people all over the world. In Mediterranean Europe, a typical image is that of a group of old people organizing improvised gatherings to talk behind the fence that protects public works. This kind of works is called "public" because they are funded by the money contributed by citizens, that is, society. Yet they are also public because these activities have their public, as any artistic performance or installation that takes place in the space of sociability par excellence of modernity: the street. The prevalent notion of public has much to do with this image: a passive audience, who is separated from the events by a visible or invisible barrier and is happy consuming whatever is offered to them. However, one of the meanings of "public," according to the Oxford English Dictionary, has deeper implications: "*concerning* the people as a whole."

Key Issues

From Spectator to Stakeholder

From Renaissance antiquarianism, archaeology has traveled a long way to become a scientific discipline and to accept that it has a responsibility toward its public. Thus, during the phase of institutionalization of archaeology as an academic discipline during the second half of the nineteenth century, an elite of intellectuals contributed, from universities and museums, to legitimize the bourgeois nation-state through teaching, writing scholarly books and articles, and developing regional and national museums. During this period, archaeology's main strategy of communication with society was the so-called educative model (Holtorf 2007a: Chapter 6, 2007b). This model was based on the communication of the results of scientific research to a learned public, which was knowledgeable about the subject. The purpose was to educate patriot-citizens, so that they would see the past in the same terms as archaeologists.

During the first decades of the twentieth century, this model continued to be in force. Experts and bureaucrats appropriated archaeological information for themselves, acted as custodians of the archaeological heritage, and adopted a paternalistic attitude, disregarding the interests of a budding civil society. The end of the Second World War and the consolidation of the Welfare State would provide the material and ideological conditions needed to insert archaeology in the dynamics of mass media. The dissemination of archaeological knowledge started to be considered as a basic function of the management of archaeological heritage. This change is epitomized in the figure of Sir Mortimer Wheeler, whose frequent appearances on TV evinced a novel compromise with the general public. However, this compromise still had its limits. The pioneer book by Charles R. McGimsey *Public Archaeology* (1972) was addressed only to professional archaeologists, heritage managers, and citizens interested in protecting archaeological remains in their neighborhoods. The immense majority of society still

remained on the other side of the fence, as a passive observer of archaeological projects. In addition, the New Museology and the growing offer of archaeological sites open to the public provided only closed narratives that were simply consumed by a certain kind of public (Merriman 1991). It is important to remember, also, that most countries continued to be entrenched in the classic model of academic communication – by archaeologists for archaeologists (Venclová 2007).

The transition from the educative model to the democratic model had its origins in the 1970s in the United Kingdom, with a remarkable development later in the United States, Canada, and Australia, where there was already an important sensibility toward the interpretation and promotion of cultural and natural heritage (McManamon 1991). During the 1970s and 1980s, the scope of interaction between archaeology and the public broadened to include all sectors of society and to actively involve amateurs in the archaeological research process. It is in this context where public archaeology, as we understand it today, emerged (Schadla-Hall 1999; Ascherson 2000; Merriman 2004; Moshenska 2009).

During the 1980s and 1990s, archaeology became public spectacle, a resource to transform depressed regions, a tool for the promotion of tourism, and a privileged arena to perform "living history." Following the technical language adopted by heritage managers, the *potential public* of these attractions is identified with the tourist/amateur who spends money to achieve enjoyable experiences set in a (pre)historic scenario (Stone and Planel 1999). This potential public is the one who crosses over to the other side of the fence for a reasonable price. However, this archaeology still does not "concern the people as a whole." The development of post-processual theory added cultural relativism, new ethical requirements, and multivocality to the agenda, as well as the de facto integration of society in all its complexity into the archaeological discourse (Hodder 2008). This brought a radical qualitative change in contemporary social archaeology: A globalized, multicultural, and complex society encompasses different publics and different approaches to heritage (McManamon 1991; Hamilakis 2011; Pyburn 2011). The generalization of the Internet during the 1990s and the emergence of social networks in the 2000s helped channel the global demand for cultural heritage by different and ever-growing social groups (Matsuda and Okamura 2011). This context partially explains the expansion of public archaeology, materialized in the creation of an international journal (*Public Archaeology*) and postgraduate courses. Public archaeology today is also influenced by the post-modern end of grand narratives, and the subsequent popularization of microhistory, cultural history, and "history from below." In the same line, the "archaeology from below" (Faulkner 2000) has evolved to overcome the unidirectional character of the discipline, which has been rooted hitherto in a noninclusive communication model. The conventional approach considers the interaction with the public an area of expertise within archaeology an optional component in scientific projects, rather than an integral part of the discipline. An archaeology from below, on the contrary extends the social relations of archaeology by involving all publics in the process of knowledge production from the beginning.

These publics include now different stakeholders, local communities, and indigenous groups who have an intimate and long-standing concern for specific archaeological artifacts, sites, and landscapes. Some of these publics, such as indigenous groups in the Americas, are very vocal and critical and directly question archaeologists and heritage managers. Grassroots movements of political dissent, such as those that agitated Spain in 2011, are also an index of the changing attitude of the public: People revolt against the passive role (as consumers of politics, industrial products, or culture) to which they have been relegated by the hegemonic capitalist order. New concepts, such as archaeological ethnography (Hamilakis 2011) or community archaeology (Marshall 2001), intend to express a more active and democratic way of dealing with these stakeholders. There is no longer a target public for archaeological knowledge, but communities, both real and virtual, rooted and global (Matsuda and Okamura 2011). From this perspective, it is assumed that archaeologists have to relinquish partial control of

their projects (Marshall 2001) and accommodate the demands of the groups with which (sometimes for which) they are working. Of course, this attitude does not prevent tensions between archaeologists and public/stakeholders to happen. These, however, existed also before, but were negated or unacknowledged. These tensions are not necessarily negative: They can be productive as well and lead to new perceptions of the past and new modes of engagement (Witmore 2009). In fact, the new understanding of "public" also entails a new notion of site: Hamilakis (2011: 406) regards archaeological sites as "a perfect borderland and an ideal zone of contact," which can lead to conflict and confrontation, "but also to detailed, sensitive, ethnographic discourses and perhaps subsequent dialogues and collaborations."

From Stakeholder to Witness

It is widely admitted today that granting public access to historical knowledge is rarely neutral and risk-free: Politics is always involved to some extent and conflict is always a possibility. This is particularly the case when archaeology delves into a dark past that has been concealed for political reasons. By making (hidden) things public, archaeology can destabilize hegemonic discourses that distort the way in which history is told. This meaning of "public" has become increasingly relevant in archaeology during the last two decades, with the growing awareness of the role played by the discipline in conflict and post-conflict situations (cf. Starzmann 2008). In countries that have suffered from war, civil and ethnic conflict, dictatorship or colonialism, it is not enough with doing research that increases social knowledge about the past. It is important to confront recent history critically and provide the tools so that people can see the past in a different way. Making a dark past public is not an easy task: Some people may not want it to be studied because they are related to the perpetrators, because it brings up memories that are too fresh and painful, or because they do not want to abandon the safety of sanitized official narratives. Archaeologists working in places of conflict and trauma have to be ready to face a divided community and to take sides. Even when people widely agree that dealing with a negative past is necessary, controversies always arise regarding how to investigate it, how to display it publicly, and how to tell the story.

In the archaeology of older periods or less controversial issues, to become part of the audience or not is to a large extent optional. However, this is not the case with the archaeology of contemporar violence. People feel addressed and their beliefs questioned. This is because collective traumas are public in the first OED sense: They concern the people as a whole. It could be argued that by unveiling the traces of atrocities, archaeology forces us to become witnesses by proxy. In that, the discipline works like what has been called "art of witness" or "testimonial art" (MacLear 1999). This is not only the art produced by witnesses themselves, but also by artists after traumatic events with the purpose of manifesting the unsayable. By forcing people to look, testimonial art and archaeology produce the same effect: They transform the public into a kind of witness – a public, therefore, with a moral responsibility. In recent decades, archaeology has become a sort of "art of witness" in different contexts. Three of the most interesting are Germany in relation to the Nazi past; Spain and the legacy of the civil war; and Argentina and the "dirty war" waged by the military. Despite being recent historical episodes, archaeology has played an outstanding role in exposing mass violations of human rights and bringing to the public arena what used to be concealed or restricted to academic debates.

Germany was one of the first countries where archaeology was put at the service of making a difficult past visible. After a generation of silence, the children of the Nazi generation decided to break the veil of silence that covered the fascist period and began a movement of recovery of historical memory which has had lasting effects in the country (Koshar 2000). Many of the popular history projects had an important archaeological component: the documentation, in everyday spaces, of traces of Nazism that had been rendered socially or physically invisible. One of the landmarks in this process was the excavation in 1987 of the former Gestapo headquarters in the heart of Berlin (Bernbeck and Pollock 2007), which had

passed virtually unnoticed in a vacant lot. The excavations, originally carried out by amateurs, captured wide public attention and provoked intense political debates. Since then, other traces of the Nazi past have been investigated in Berlin and identified with signs, so that people can be aware of this hidden layer of the city's history (Braun 2002). The goal of the project is not just to make things public, but to *keep* them so. The question is: How to sustain public attention in a traumatic past?

In Argentina, the search for the 30,000 *desaparecidos* ("disappeared") during the military regime started only 2 years after the end of the dictatorship (1976–1982). Forensic work has been later complemented with other initiatives, such as the archaeological investigation of clandestine detention centers, the study of the material culture associated to the *desaparecidos*, and the public display of sites of torture and prisons (see examples in Funari et al. 2010). All these projects have made the crimes of the dictatorship public, but they have also been fraught with controversy: whether to recover or not buried human remains (Crossland 2000), how to turn detention centers into museums, what narrative has to be offered (Parsons 2011), etc. These are debates in which archaeologists and other scholars have just one voice among many others (victims, relatives, authorities, and associations). The Argentinian case poses questions that are pertinent for public archaeology as a whole: Who has the right to decide how to make the past public? How can a dark past be made public without trivialization? What kind of public is a victim or a victim's relative?

If the Germans had to wait for a generation to make a painful history public and the Argentineans only a few years, the delay in Spain has been much greater: Three generations passed since the beginning of the war (1936–1939) for the Spaniards to be capable to fully address the legacy of war and dictatorship. As in the other two cases, it was grassroots associations that took the initiative and since 2000, they have excavated – with the help of archaeologists and forensic scientists – around a thousand unmarked graves, mostly containing the remains of some of the 150,000 people assassinated by the supporters of General Franco (Ferrándiz 2006; Renshaw 2011). Exhumations were part of a renewed interest in the history of the conflict and the dictatorship. Thus, in addition to the recovery of buried bodies, different projects have been developed on concentration camps, prisons, monuments, and battlefields (González-Ruibal 2007). The process has led to a significant shift in the collective memory of Spaniards and has triggered important political and legal changes at the national level. It has also produced a greater awareness of the (material) legacy of the dictatorship. Although archaeologists, as in the German case, have not been the protagonists, they have decisively contributed to making things public, by bringing in scientific methods and modes of dissemination. The exhumation of mass graves and other activities have not been free of bitter controversies, but these have also helped to clarify the political panorama of Spain, by revealing the extent to which the dictatorial past still conditions the democratic present.

Future Directions

Despite great advances during the last three decades, academic traditions continue to privilege the educative model in archaeology, whose discourses are neither directed to the general public or local communities. The same can be said of different projects devised from above (such as those promoted by administrations), in which the public is conceived as the human resources needed to fill cultural containers. From these parameters, it is difficult that a public archaeology (sensu Shadla-Hall 2006), and even less a community archaeology (sensu Marshall 2001), can be consolidated. Besides, the privatization of archaeology at a global scale promotes commercial archaeology, which is more profitable, but does not usually take into account amateurs and citizens in the process of archaeological research.

However, if we have learnt something in recent years, it is that publics can be very active and take the initiative in process that involves historical memory or the assertion of cultural rights: The

things that concern the people as a whole elicit passionate responses. This has been proved in the three cases mentioned here: the archaeology of dictatorship in Germany, Argentina, and Spain. With the global spread of democracy and minority rights, publics are more varied and vocal than ever. Instead of feeling threatened by them, archaeology should face the challenge of engaging in social debates and political controversies. The alternative to this is remaining in an ivory tower and become less and less socially relevant.

Publication in Field Archaeology

Martin Carver
Department of Archaeology, University of York, Kings Manor, York, UK

Introduction and Definition

Every publication in any field is designed for the people who are intended to read it. Archaeological fieldwork is carried out for different sectors and sponsors and it therefore generates a variety of output. A recent overview proposed eight different modes of publication designed to serve eight different types of "consumer" (Fig. 1).

Key Issues

The preparation of a *field record* (no. 1) is a primary duty of the fieldworker, whether engaged in CRM or research. These records are generally stored in an archive within the museum that retains the assemblages of artifacts and biota. In principle, records and assemblages are public property and remain accessible in perpetuity. In practice museums often find this difficult to achieve but hope to make the material available to researchers and special interest groups. The increasing range of records and material retained by excavators combined with the enormous quantity of material generated by CRM is creating a major problem of long-term storage for industrialized countries. This is one reason for the development of the online *lab report* (or Field Report) (no. 2), which sets out to present a complete account of the main discoveries from fieldwork in a digital form. This will include summaries of the primary records, an album of selected photographs, an atlas of the main spatial form and relationships, site journals and interpretations made on site, and analyses made in the laboratory after fieldwork was completed. These analyses may include studies of stratigraphy, artifacts, animal bones, plant remains, and scientific dating. In many cases the specialist reports in their original form may appear only in this medium, their essence being summarized for printed forms. The *Archaeological Data Service* (http://ads.ahds.ac.uk) is a major service provider in this field, hosting online archives for research projects as well as many thousands of client reports from CRM operations which are otherwise inaccessible.

The production of a *Client Report* (no. 3) is normally a condition of contract for the CRM firm that undertakes fieldwork in advance of development. The "client" is the organization that paid for the archaeological work. In regulated countries this is often local or national government. In deregulated countries it is more usually the organization that is undertaking the development; archaeology is included in its costs. In both cases, the clients or their consultants provide strict instructions about the content of the report and the timetable for its delivery. These contents include details of the location, the work done there, the methods used, and the discoveries made. In the current profession, many of the methods are standardized and repeated in successive client reports.

MODE	CONTENTS	MEDIUM	CLIENTS
1. Field Records	Site records, primary data	Hard copies	Sponsor, Other researchers
2. Lab Report	Commissioned studies and analyses	e-repository	Sponsor, other researchers
3. Client Report	Description of the investigation and results	Hard copy with limited distribution ["grey literature"]	Sponsors
4. Research Report	Description of the investigation, findings, their interpretation and context	Article (hard copy or on-line), monograph with multiple distribution	Researchers
5. Popular book	Abbreviated research report	book	The public
6. Popular output	Selected significant aspects	Magazine articles, site guide, TV programmes	The public
7. Display	Selected significant aspects	Exhibitions in museums,	The public
8. Presentation/ Interpretation	The site and its surviving parts; local trails	Conserved monuments; display panels;AV	The public

Publication in Field Archaeology, Fig. 1 Modes of publication. (After Carver 2009: 316)

The value of the archaeological discoveries themselves is expressed in terms of their *significance*, a measure of how far they have added to knowledge. However, CRM projects rarely include research time, and so client reports can rarely expect to explore this significance in the wider context of modern research. For this reason, the majority of client reports remain as "grey literature" delivered to the client or at best placed in an online archive where it is generally accessible (see above).

Research Reports (no. 4) are intended to report the most significant new discoveries of the day. They are, accordingly, selective in two senses: first, only fieldwork productive of important research is eligible for consideration, and of that, only carefully selected data and succinct argument are appropriate for publication. Research publication is subject to peer review, undertaken on behalf of publishers to ensure the highest standards of integrity and reasoning. The criteria for acceptance usually run along the lines: "Was there a research question?" "Did it need to be addressed?" "Are the results clearly presented, validated, and discussed?" and "Is the conclusion credible?" There have always been numerous other forms of open-ended, unspecific, imaginative, and non-scientific writing about the past, but few have been successfully applied to the publication of results of fieldwork.

The current research community in archaeology overwhelmingly prefers paper-copy publication in journals or monographs over data-rich digital repositories. Research publication is therefore expensive, another reason that it remains competitive and selective. It should also be noted that the main beneficiary of such selectivity is the reader. By filtering the mass of information and opinion that is generated by the archaeological community, the publishing industry hopes to select the fieldwork of most significance and most lasting value at the least cost to researchers and other readers.

The content of a research report will include the basic information about the purpose of the project, the research questions that were addressed, where it took place, the theoretical basis for the design, the methods used, and the results obtained. A site model is argued on the basis of selected analyses of assemblage, space and sequence, and a free-ranging account of its context and wider significance presented in a discussion section. The conclusion assesses the success in answering the questions expressed in the

original Project Design, presents new ones, places the fieldwork results in history or prehistory, and announces the planned future of the archive, the site, and its environs.

Members of the public, and indeed students when they are starting out, may not have the background to appreciate or assess research reports. If a field project has become well known, it may become the subject of a range of more general outputs. "Popular" books (no. 5) attempt to place the archaeological discoveries in the mainstream. Commercial publishers do a wonderful job here, usually ensuring good quality and taking the financial risk on themselves. Mainstream publishers may produce a range of summaries and pictures in magazines, newspapers, and on TV (no. 6) over which the field archaeologist generally has less control but may still welcome them on the basis that "there is no such thing as bad publicity."

Direct communication with the public is available in two other media. In exhibitions (no. 7), the findings of fieldwork may find vivid expression in a museum, where artifacts and structures and their sequence are brought together. Some sites, particularly those which have been the subject of research projects (less so those excavated in advance of development), are still conserved and may be visited by members of the public. The art of presenting sites (sometimes known as "interpretation") is to explain to visitors what they can still see and relate what was found and what it might mean (no. 8). This is undoubtedly a form of publication and a special one since it takes place in the landscape, that historic environment which field method sets out to enhance.

Pueblo Bonito

Catherine M. Cameron
Department of Anthropology, University of Colorado, Boulder, CO, USA

Introduction

Located in Chaco Canyon, in northwest New Mexico, Pueblo Bonito is the greatest of the Chacoan "great houses" (Fig. 1). A massive stone structure built in a "D" shape, Pueblo Bonito consisted of terraced rooms reaching four or five stories tall at the rear and stepping down to a large, divided central plaza. It is known not only for its architectural beauty (*Pueblo Bonito* means "pretty town" in Spanish) but also for the wealth of exotic artifacts found within its rooms – an abundance unparalleled at any other site in the northern Southwest. Pueblo Bonito has been extensively studied for over a century. The Hyde Exploring Expedition (1896–1899) led by George Pepper (1920) and the National Geographic Society Expedition (1920–1927) led by Neil Judd (1954, 1964) excavated almost the entire ruin, revealing the architectural history of the site and recovering hundreds of thousands of artifacts. Archaeologists since then have made comprehensive use of Pepper's and Judd's work in numerous books and articles (see Neitzel 2003 for a recent compendium).

Construction began at Pueblo Bonito in the mid-ninth century and continued through the middle of the twelfth century (Lekson 1986; Windes and Ford 1996). During much of this period, Chaco Canyon was a place of extraordinary power, the focus of a large social and political system that encompassed much of the northern Southwest (northwest New Mexico, southwest Colorado, southeast Utah, and northeast Arizona) and was characterized by widely scattered great houses and their surrounding communities (Lekson 2006, 2009). Prehistoric roads radiated out across this landscape, leading into and out of great houses, suggesting an unprecedented level of connection and hierarchy in the Ancestral Pueblo world.

Pueblo Bonito, Fig. 1 Reconstruction of Pueblo Bonito. Note the platform mounds in front of the building and the large ponderosa pine tree in the plaza. The tree was apparently an important element of plaza space at Pueblo Bonito. (Courtesy of Dennis R. Holloway, Architect)

The American Southwest is an arid region, but Chaco Canyon is especially dry and treeless. Why it was selected for monumental construction of great houses is a subject of extreme interest to scholars today. The Chaco Wash only occasionally contains water, although a slightly more favorable climate may have made the Canyon more inviting when Pueblo Bonito was first constructed. However, Chaco Canyon *is* one of the most conspicuous landforms in the relatively flat central region of the San Juan Basin.

Pueblo Bonito was not the only great house in the Canyon. It is one of almost a dozen that were built along the north side of the Canyon bottom or on the mesa to the north of the Canyon. Pueblo Bonito and other great houses, both inside and outside Chaco Canyon, are argued to have been the homes of powerful leaders, while ordinary people lived in small hamlets surrounding the great houses. In Chaco Canyon with its many great houses, this pattern is expressed in a linear pattern with the homes of ordinary residents located primarily along the south side of Chaco Canyon, opposite Pueblo Bonito and the other great houses.

Definition

The sheer northern walls of Chaco Canyon provide a dramatic backdrop for Pueblo Bonito. It was built facing "South Gap" a break in the south Canyon wall that allowed visitors a dramatic view of this impressive building. It was the first of what eventually became a cluster of great houses in the central part of the Canyon that has been called "Downtown Chaco." From the cliff-top above, the entire building appears in plan view and is still an awe-inspiring place, even though it now lies in ruin. In facing Pueblo Bonito toward the southeast, its builders were following normal Puebloan siting practices that maximized solar energy during the cold winter months. Backed up against the Canyon wall, the building was also protected from northerly winter winds. Oddly, the structure was built under an enormous but precariously balanced pillar of sandstone that had split from the Canyon wall. Called "Threatening Rock" by modern visitors, the distinctive rock formation was apparently an important part of the siting of the building (Stein et al. 2007).

Pueblo Bonito comprised as many as 600 rooms built of finely shaped and chinked sandstone masonry. It was more than 150 m long and 100 m wide, covering almost a hectare. The final form evident today was the result of more than 300 years of construction and remodeling (Lekson 1986). The original building, constructed between about A.D. 860 and the early 900s, was in the style of normal domestic buildings of the time, a southeast-facing arc of rooms fronted by a series of round rooms. Only this original core of rooms was a "scaled-up" version of normal Puebloan architecture: rooms were two to four times as big as normal Puebloan rooms and

included some of the earliest multistoried buildings in the Southwest (Lekson 1986). This part of the building was used for burial of high-status individuals, apparently sacred space around which the rest of Pueblo Bonito was constructed (Plog and Heitman 2010). Around A.D. 1020 when the rear wall of the original building began to collapse, an enclosing wall of improved masonry was built around it to ensure that it continued to stand (Lekson 1986:132–134).

Subsequent construction continued until the mid-1100s with extensive construction episodes in the A.D. 1040s and 1080s (Lekson 1986; Windes and Ford 1996). This construction expanded the original D-shape of the building, adding rows of rooms adjacent to the plaza (covering some of the original round rooms), extending the "wings" of the D, and enclosing the plaza with a narrow wall of rooms. Pueblo Bonito was never a static structure but an active and a living part of Puebloan construction whose intended trajectory from creation through normal processes of decline and decay has only been arrested by modern institutional efforts at preservation.

Most of the rooms that composed Pueblo Bonito were square or rectangular, but some were round. Round rooms were generally located close to the plaza or in the plaza adjacent to the main building. Round rooms were likely the major living spaces for the leaders who inhabited Pueblo Bonito (Lekson 1986; these rooms are called "kivas" by some scholars who imply a religious use). Rectangular rooms were very large, ranging from 10 to almost 50 m^2, with some variation corresponding to the distance of the room from the plaza (Lekson 1986: 51). These rooms often formed suites, indicated by positioning and connecting doorways. The presence of hearths in some plaza-facing rooms suggests that they may also have been the principal living rooms. Rooms in the rear and lower stories would have been dark and airless and may have been used for storage of food and the quantities of exotic material that apparently poured into this settlement. Some rooms have the remains of large platforms that might have served as storage shelves (Lekson 1986: 46–48). But archaeologists have found very little direct evidence of what might have been stored.

The straight side of Pueblo Bonito's "D" was formed by a narrow block of rooms that made the plaza into an enclosed space. Inside the plaza, large subterranean round rooms (13 to almost 16 m in diameter) called "great kivas" housed ceremonial activities. Great kivas were already important ceremonial buildings long before the construction at Pueblo Bonito began but developed a distinctive Chacoan form in Chaco Canyon during the eleventh century (Van Dyke 2007). As many as four great kivas may have been built in Pueblo Bonito's plaza at various times during its history, two or three of which may have been in use at one time. They were built on either side of a north-south wall that divided the plaza into eastern and western halves, a duality that has other manifestations in the Chacoan world. Van Dyke (2007: 117–121) explores the ceremonial activities that may have taken place in Chaco Canyon's great kivas (others were found at other great houses or away from great houses in other parts of the Canyon).

In front of the plaza are two large walled mounds built up of trash and other materials and separated by a road or pathway that may have led directly to an opening into the plaza wall (Fig. 1). These trash mounds may have served as ceremonial platforms, as they were covered with a plaster surface at least during part of their use life (Lekson 1986: 143–144; Windes and Mathien 1987: 618–634)

As part of Downtown Chaco, Pueblo Bonito was surrounded by an extensively built landscape that included not only other great houses but also roads, staircases, earthen causeways, and other features (Lekson 2007, 2009, 2015; Stein et al. 2007). Prehistoric roads led from a great house on top of the mesa north of Pueblo Bonito (called Pueblo Alto), descending into the Canyon at a wide formal staircase just around the corner from Pueblo Bonito. Other roads descended from the north mesa at other points on the north Canyon wall or entered Downtown Chaco from the south. Stein et al. (2007) have identified an earthen platform constructed at the base of Threatening Rock behind Pueblo Bonito,

a possible elevated road surface extending from the east end of the eastern platform mound, as well as other earthen features.

Key Issues/Current Debates/Future Directions/Examples

An animated debate surrounds the function of Chacoan great houses. Pueblo Bonito is central to this debate. Pueblo Bonito is the archetypical great house but is also in many ways unique in the Puebloan world. The debate can be briefly summarized as a series of questions: How many people lived in Pueblo Bonito? Who were they and what did they do there? What was the connection between the people who lived in Pueblo Bonito and other Chaco Canyon buildings to the great house communities spread out across the northern Southwest? Although consensus on these questions has not been reached by Chaco scholars, a review of contrasting interpretations highlights the distinctive role Pueblo Bonito played in the Chacoan world.

The number of people inhabiting Chaco Canyon and its great houses has been a topic of discussion from the very first archaeological investigations there. Initial estimates in the tens of thousands have been revised downward to as few as 1000 (Windes and Mathien 1987: 383–406). Recently Pueblo Bonito's momentary population has been assessed at only 12 households or 70 residents (Bernardini 1999). Such a small population in Pueblo Bonito's vast architectural space implies that only special people resided here, but what they did there is also a point of contention. One group of scholars argues that great houses, especially Pueblo Bonito, were elite residences and that Chaco Canyon was the center of a hierarchical political system that covered much of the northern Southwest during the tenth and early eleventh centuries (Lekson 2006, 2009, 2015; Sebastian 2006). Other scholars see a much more egalitarian structure in Chaco Canyon with priests serving as ritual leaders and a hinterland that emulated Chacoan practices but was not controlled by Canyon ritual leaders (Kantner and Kintigh 2006; Mills 2002).

The evidence on which this argument turns includes Chacoan architecture, burials, and imported goods, each of which is most remarkable at Pueblo Bonito. Pueblo Bonito is the largest of the great houses, and most scholars agree that great houses can be considered monumental architecture, in other words, large-scale public construction projects. However, some scholars argue that the variability in great house construction outside Chaco Canyon demonstrates the independence of outlying Chacoan communities from Canyon control (Kantner and Kintigh 2006). Other scholars counter that Chaco Canyon itself includes a high degree of architectural variability including considerable change through time in construction methods especially at the longest-lived great house, Pueblo Bonito (Lekson 2006, 2015). Contrasting views of the existence of hierarchy in Chaco Canyon also extend to the labor force that built great houses: Were laborers coerced by leaders who lived in these "palaces"? Or were they voluntary laborers who converged on the Canyon periodically to build great houses under the direction of benign priests?

Pueblo Bonito has a set of extraordinarily rich burials, unparalleled in the Puebloan world, which have been central to discussions concerning Chacoan complexity. Akins (2003) has identified 131 burials at Pueblo Bonito, most located in two clusters of rooms in the oldest part of the building that she terms family burial facilities. But these were no ordinary families. At least one of these sets of burial rooms also functioned as a repository for elaborate ceremonial paraphernalia. Arguments about the nature of hierarchy in Chaco Canyon have focused on the two richest burials, Burials 13 and 14, two males who were found in Room 33 beneath a carefully constructed plank floor and were accompanied by more than 30,000 objects, including 25,000 pieces of turquoise (mostly beads), more than from all other Southwestern sites combined (Plog and Heitman 2010: 19622). Cylinder jars, wooden ceremonial sticks, a shell trumpet, turquoise- and shell-encrusted baskets, and wooden flutes were also found here. Additional burials continued to be placed above the plank floor and in immediately adjacent rooms, perhaps as secondary burials, into

the late eleventh or early twelfth century; these adjacent rooms were also full of exotic goods.

Scholars who see political hierarchy in Chaco Canyon have argued that these two individuals were powerful political leaders (Lekson 2006; Sebastian 2006). Other scholars have pointed to the fact that these two males, thought to have been deposited in the early eleventh century, were the only evidence of elite rulers in the over 300 years of Chaco's existence. This argument has been recently addressed by Plog and Heitman (2010) who present startling new data about the Pueblo Bonito burials. They obtained C-14 dates on human remains found here and confirm that these internments were actually some of the earliest activities at the site, dating perhaps to the late ninth century. They suggest that these two males could have been among the founders of Pueblo Bonito, beginning a tradition of social differentiation that continued into the late eleventh or early twelfth century. Even more startling, a recent DNA study revealed that at least some of the burials in Room 33 were part of a multi-generational matrilineal descent group of related mothers and daughters, grandmothers, and grandsons (Kennett et al. 2017). Pueblo Bonito, then, functioned at least partly as a long-lived sepulcher where only the most powerful members of Chacoan society were buried.

Evidence of the high status of the residents of Pueblo Bonito is also apparent in the exotic goods found there, both with burials and in other parts of the site. These objects were in some cases unique and, in others, occurred in quantities far in excess of those found at any other sites in Chaco Canyon or indeed the entire Ancestral Pueblo world. Much of this material was imported from a considerable distance (Toll 2006): turquoise from mines 100 miles to the east, shell (including shell trumpets) from the Pacific Ocean, macaws, copper bells, and cacao from Mesoamerica. Cacao may have been made into a frothy chocolate drink served in cylinder jars that have been found almost exclusively at Pueblo Bonito (Crown and Hurst 2009; see also Crown et al. 2015). Macaw feathers may have been made into elaborate "badges of office" distributed to leaders from distant great house communities who visited Chaco Canyon (Lekson 2015).

For more than 300 years, Pueblo Bonito was the most important building in the northern Southwest. This elaborately built structure was home to a small population of people who have been variously described as powerful political leaders or less powerful ritual specialists. Ceremonial activities certainly took place in Pueblo Bonito, both in the central plaza, atop the platform mounds, and in the great kivas located in the plaza. Other ritual activities apparently involved the internment of powerful individuals in a mortuary crypt located in the oldest part of the building. During the many centuries of its use, Pueblo Bonito was a living entity, growing and changing with each generation. Pueblo Bonito was not just another great house; it was "the" great house, the center of the Chacoan regional system. Although Chacoan scholars may continue to debate the nature of that system, few will deny Pueblo Bonito's centrality.

Introduction

The Andean Mountains are a formidable chain of mountains that form the backbone of South America. They range over 6000 m in elevation and consist of a succession of mountain ranges and plateaus, generally in a N-S direction, with the exception of a southeastward bulge that forms in southern Peru and northern Bolivia. The different environmental zones that characterize the Andes are mostly defined in terms of elevation, rainfall, and latitude and include coastal deserts, forests, highland scrub, and grasslands, also known as *Puna*, which lies above 3000 masl.

Late Pleistocene hunter-gatherers began exploring the Puna approximately 12.8 ka and faced the challenges that characterize extremely high altitudes: cold temperatures and hypoxia. Notwithstanding, these populations adapted culturally and biologically to these conditions and very early on began exploiting two important natural resources – wild camelids and obsidian. The increasingly arid conditions that prevailed in the Puna during the mid-Holocene ca. 8 ka drove some populations away from marginal areas. However some populations, like those in the southern range of the Puna, engaged in the early

phases of camelid domestication and in a two-way interaction with populations living in the lowlands to the east of the Andes, as social relations with those ecozones would have allowed Puna foragers to call on neighbors in times of need. This interaction lasted throughout the Formative and the Late periods.

Definition

The Puna, a *Quechua* word meaning high peaks and grasslands of the Andes, is a high elevation region that lies between 3000 and 4800 masl, between 10° and 27° latitude South, and covers regions of central and southern Peru, western Bolivia, northern Chile and northwestern Argentina. It extends north to south for approximately 2000 km and about 250 km east to west. The Puna includes the Altiplano of Bolivia and southern Peru. It is characterized by low humidity, with estival rainfall varying between 800 and 50 mm annually. Rainfall decreases in a N-S and E-W gradient, and some of the driest regions in the Puna lie in its SW corner. In general, productivity is low. Atmospheric pressure is low and temperature has a wide daily range. The average annual temperature is 9 °C, with a strong diurnal and seasonal variation. Given the rainfall gradient, the Puna is traditionally divided into three zones: Wet Puna (with the highest rainfall), Dry Puna and, Salt or Desert Puna (with the lowest rainfall). Each of these environmental zones constitute long and narrow strips that extend roughly in a N-S direction from Central Peru to NW Argentina and northern Chile. The Wet Puna is the easternmost strip and includes the area of Lake Titicaca on the Peru-Bolivia border, the Salt Puna is the southernmost and westernmost strip and includes the arid areas dotted with saltpans (*salares*), and the Dry Puna lies between both (Fig. 1). Rainfall in the Dry and Salt Puna is very low – annually below 250 and 50 mm, respectively. Further, there are areas in the Salt Puna that do not see any rain in 10 years, and thus it constitutes a doubly extreme environment given its great elevation and aridity.

The focus of this entry is on the Argentine Puna. (For entries on the archaeology of Southern Bolivia, the Atacama Desert, and the Central Andes, see "Cross-References" section.) This region is a high intermontane plateau and an endorheic basin that extends from the border with Bolivia (latitude 22°S) to approximately latitude 27°S and from the Cordillera de Los Andes on the border with Chile to the chains of mountains that conform the eastern Puna rim.

Vegetation varies with elevation and is marked by the presence of shrub steppes (*Adesmia*, *Fabiana*, *Baccharis*, and *Parastrephia* genera) at elevations below 3900 m and grasslands (*Festuca*, *Stipa*, and *Azorella* genera) at elevations above 3900 m. Around rivers, streams, lakes, and saltpans (*salares*), there are wetlands (*vegas*) that are characterized by soft grasses dominated by Juncaceae and Cyperaceae families.

Faunal communities include vicuñas (*Vicugna vicugna*), which mainly graze in the *pajonal* grasslands, and domesticated llamas (*Lama glama*), which mostly feed off wetland grasses. Large rodents (Chinchillidae family) are found in *quebrada* rockeries, whereas birds (*Rhea pennata*, Phoenicopteridae family) are common around water sources. Foxes (*Pseudalopex culpaeus* and *P. griseus*) and pumas (*Puma concolor*) are the main predators.

Historical Background

Traditionally, research in the Argentine Puna has focused on three main regions: (a) the Salt Puna in the province of Catamarca; (b) the Dry Puna in the province of Jujuy, and (c) the transitional area between the Dry and Salt Puna, often referred to as the Puna of Salta, in the province of Salta.

The Salt Puna

The decade of the 1950s marked the beginning of archaeological research in this region, when Pedro Krapovickas led archaeological surveys and excavations in the area of Salar de Antofalla, at Tebenquiche Chico. This research continued several decades later, under the direction of Alejandro Haber, who also conducted research in the Archibarca area (Haber 2009). Archaeological surveys were also carried out in the Antofagasta

Puna, Archaeology of, Fig. 1 The Wet Puna, Dry Puna, and Salt Puna in South America

de la Sierra area, in the 1970s, at La Alumbrera site and were followed in the 1980s by Carlos Aschero's work in the Laguna de Antofagasta basin, specifically at a deeply stratified site – Quebrada Seca 3 – and other rock-shelters, such as Cueva Salamanca 1, Peñas de la Cruz 1, and Peñas de las Trampas sites. Together with a team of students, this research continued in the 1990s and 2000s at several rock-shelters and open-air sites (Fig. 2), which resulted in the construction of a 10,000-year-old chronological sequence of human occupation beginning with the earliest date of 12.4 ka at Peñas de las Trampas 1 site (Aschero 2014).

The Dry Puna

The 1970s also marked the initiation of systematic research on the eastern rim of the Dry Puna at several rock-shelters in the Quebrada de Inca Cueva – namely, Inca Cueva 4 site (3500 m), one of the oldest sites in the Puna region, dated to 12.7 ka. This research was soon followed in the 1980s and 1990s by a series of other discoveries of sites with equal or slightly greater antiquity, such as Pintoscayoc, Huachichocana, and Yavi ca. 12.8 ka. More recently, there has been in the area of Susques, at the Hornillos 2 site (Fig. 2) (Yacobaccio et al. 2017).

The Puna of Salta

In the Puna of Salta, archaeological research began in the 1990s in the San Antonio de Los Cobres area and continued in Salar de Pastos Grandes, at Alero Cuevas, a site with a deep chronology began in the 2000s. More recently, the Abrigo Pozo Cavado site has been excavated in the Salar de Pocitos (Fig. 2) (López et al. 2013; Muscio and López 2016).

Key Issues/Current Debates

Timing of the First Puna Occupations and Strength of the Archaeological Signal

The earliest sites in NW Argentina are located in the Dry and Salt Puna, at elevations ranging 3500–3800 m. Around 12.8–12 ka, that is, within 2000 years of the earliest, well-established dates for human occupation in South America (ca. 14.5–15 ka) such as those from Monte Verde and Huaca Prieta sites, and during a period of wetter and warmer conditions of the Coipasa paleoclimatic event, small populations of foragers

Puna, Archaeology of, Fig. 2 Areas of study and archaeological sites: (1) the Dry Puna (Quebrada de Humahuaca and Susques), (2) the Puna of Salta (Pastos Grandes and Salar de Pocitos), and (3) the Salt Puna (Antofagasta de la Sierra). Obsidian sources: (Z) Zapaleri, (V) Caldera Vilama 1 and 2, (T) Alto Tocomar, (R) Ramadas, (Q) Quirón, (A) Archibarca, (O) Ona, (SH) Salar del Hombre Muerto, (C) Laguna Cavi, (P) Cueros de Purulla-Chascón, (VA) Valle Ancho

carried out the initial exploration and colonization of these high elevations. It would take another millennia for foragers to establish repeated occupations at elevations above 4000 m – at sites such as Hornillos 2 and Quebrada Seca 3, both at 4100 m, and Alero Cuevas site at 4400 m (11.2 ka) (Fig. 2). A recent time series analysis of radiocarbon dates suggests that during the early millennia of this colonization process, there were fluctuating periods of dispersion and retraction of populations, but overall there was a successful establishment of human populations in the Puna that paralleled those of the Chilean Puna (Muscio and López 2016; Yacobaccio 2017).

The presence of human occupations ca. 12.8 ka in the Argentine Puna, which is on the eastern slope of the Andes, implies that if migration routes proceeded in a north-south direction and along the Pacific coast, as is generally accepted, there must be evidence of human activity at earlier sites in the Atacama Desert and the Bolivian Altiplano. A survey of sites and their associated radiocarbon dates, however, shows that the earliest non-coastal sites in Chile are coetaneous with sites the Argentine Puna – Quebrada Maní 12 site (1200 m) in the Pampa de Tamarugal (Latorre et al. 2013) with dates that span 12.8–11.7 ka – as well as sites such as Tuina and San Lorenzo in the Salar de Atacama region and Salar de Punta Negra site (3000 m) ca. 12.6–10.2 ka – and one site in the Bolivian Altiplano – Cueva Bautista (3900 m) 12.8 ka (Capriles et al. 2016). Therefore, it is reasonable to expect even earlier sites either west or north of the Dry and Salt Puna in NW Argentina, unless the entry route into the Argentine Puna was from the mountain forests (*yungas*) to the east, as the very early presence of plant species from this ecozone at Dry Puna sites suggests (Yacobaccio 2017).

Interaction with the Eastern Lowlands

There is plenty evidence of contact between Puna hunter-gatherers and foragers inhabiting the South American eastern lowlands, as well as with the Pacific coast. This is particularly revealed, in the Salt Puna, in: (a) archaeological contexts ca. 10–6 ka that include spear shafts made of wooden canes (*Rhipidocladum newmannii*, *Salix humboldtiana*, *Chusquea lorentziana* Griseb.), grinding stones with *Acrocomia aculeata* palm starch residues, and *Trichocereus pasacana* cactus thorns, and (b) funerary contexts ca. 9.5–1 ka with marine and freshwater shells, cords of *Acrocomia* sp. and *Bromelia* sp. fiber and ceramic containers that resemble eastern lowland styles (López Campeny et al. 2017; Martínez 2014). The natural habitats of these perishable materials are the eastern lowlands, mountain forests (*yungas*) and even the Chaco plains distant up to 450 km. These great distances indicate that some degree of contact between these different ecozones was well established by 10 ka, that is, within a few millennia after the initial colonization process of the Puna (Pintar and Rodríguez 2015). The presence of these allochthonous materials reveals that forager lifeways were part of a much larger macro-regional open system.

The issue of complementarity (direct access, exchange, mutualism, and/or buffering) is difficult to assess archaeologically, given the overlapping signals of each of these possibilities. On the one hand, it is possible that nonlocal elements were acquired through the existence of wide social networks extending up to 450 km that facilitated the circulation and exchange of plants, animals, and genes through reciprocity between foragers in the Puna and those in the eastern lowlands, Pacific coast, and Atacama basin. On the other hand, high degrees of mobility could also have enabled foragers in the Puna to procure resources from neighboring ecological zones through logistical mobility. When climate and environment became increasingly unpredictable during the arid mid-Holocene, inter-regional contacts probably increased between Puna and lowland foragers. So by establishing and maintaining social relations with their lowland neighbors – in the form of kinship ties, trade partnerships, alliances, and inter-regional reciprocal gift giving of tokens and non-subsistence raw materials – Puna foragers would have been able to call on those neighbors and eventually been granted access to resources in times of need (Aschero 2014; Pintar and Rodríguez 2015).

Research in the lowlands to the east of the Argentine Puna (Infiernillo, Tucumán province) has recently commenced, and the discovery of

projectile points made of Puna vulcanite and obsidian at Taller Puesto Viejo 1 site, east of the Santa María river, reveals a two-way interaction mechanism that was already in place by ca. 10 ka (Martínez et al. 2013).

Obsidian Use and Exchange Networks

Provenience studies carried out in the Argentine Puna over the last 15 years have identified 12 obsidian sources that extend 600 km in a N-S axis, from the trilateral border between Argentina, Bolivia, and Chile to the south end of the Argentine Puna. These sources include Zapaleri, Vilama 1 and 2, Alto Tocomar, Quirón, Ramadas, Archibarca, Ona-Las Cuevas, Salar del Hombre Muerto, Cueros de Purulla-Chascón, Valle Ancho, and Laguna Cavi (Fig. 2), all of which are located between 3600 and 4600 m.

The geochemical identification of artifacts found at sites in the Dry and Salt Puna has revealed the use of different sources, suggesting a geographic restriction of hunter-gatherer mobility within possible territorial ranges that did not overlap. The obsidian sources at Archibarca, Ona, Salar del Hombre Muerto, Laguna Cavi, and Cueros de Purulla-Chascón were used by groups of hunter-gatherers inhabiting sites in the Salt Puna throughout the Early and Middle Holocene period and indicate a regional circumscription of their territorial ranges (Pintar et al. 2016). However, hunter-gatherers that occupied sites in the Puna of Salta and the Dry Puna used sources such as Quirón, Tocomar, Ramadas, Vilama, and Zapaleri (López et al. 2013; Yacobaccio et al. 2013).

The pattern of Early and Middle Holocene obsidian use by foragers in the Salt Puna appears to have laid the foundation of one of two mutually exclusive obsidian distribution spheres that were established by sedentary communities dependent on agriculture and camelid pastoralism ca. 2.3 ka in NW Argentina. Obsidian predominantly from Ona and to a lesser extent Cueros de Purulla circulated along the southern part of the Argentine Puna and the valleys to the east with a range of 350 km. A second obsidian distribution sphere, centered on the Zapaleri source, has been identified in the Dry Puna (Escola et al. 2016). These studies suggest that obsidian procurement and exchange networks in NW Argentina, which relied on llama caravan traffic beginning in the Formative and lasting into the Late period as suggested by petroglyphs (Martel et al. 2017), have a long tradition, the roots of which are traced back to the mid-Holocene, a period of extreme aridity in the Puna as a whole (Pintar et al. 2016). Additionally, during this time period and the early Late Holocene (ca. 5–4 ka), the obsidian sources represented in the Puna of Salta have been identified as the local Quirón source. Further, the production of blade technology in this region, which might have been used as a form of territorial identity, suggests a lower residential mobility and a greater spatial circumscription in this region that could have resulted from population aggregation (López et al. 2013).

Llama Domestication and Habitat Fragmentation During the Mid-Holocene

For thousands of years, camelids have been an integral part of the lives of Andean people. Although the debate surrounding the origins of camelid domestication goes back several decades, there is agreement at a macro-regional level that it occurred during the mid-Holocene, ca. 7.4–4 ka. Recent isotopic analyses on camelid bones in the Dry Puna suggest the presence of a "llama-sized" camelid at Hornillos 2 site ca. 7.4 ka, whereas the analyses of camelid fleeces reveal fibers corresponding to a "llama pattern" ca. 5.6 ka, and finally, osteometric analyses in the Puna of Salta and in the Salt Puna show the presence of *Lama glama* ca. 4 ka (Aschero et al. 2014; López and Restifo 2014; López et al. 2013; Reigadas 2014; Yacobaccio et al. 2013).

Moreover, a detailed study of NISP values from 27 sites/levels and diversity indices suggest a specialization in camelids ca. 6.2 ka, which coincides with the late mid-Holocene (or mid-Holocene II). Yacobaccio (2013, 2017) suggests that protective herding of camelids – protection from nonhuman predators and access

to pastures, which would allow habituation and specialized hunting – began during the most arid phase in Puna as a result of fragmentation of the environment that was amplified by habitat loss during this dry phase, a time that also saw a decrease in the anthropogenic signal (Muscio and López 2016) and the appearance of blade technology in the Dry Puna (but not Salt Puna) (Yacobaccio et al. 2017).

Further, there is consensus among Argentine archaeologists that the process of domestication was the result of an intensified relationship between foragers and camelids that began in the Early Holocene, and which allowed for the increased use of all camelid parts, not only meat but bones, grease, marrow, sinew, hides, and fleeces as well (Mondini and Elkin 2014).

Domestication of Plants

Most archaeologists agree that the transition from hunting and gathering to a mixed economy that included food production occurred during the second half of the mid-Holocene and early part of the Late Holocene, ca. 6–4 ka. The intimate knowledge of the landscape and their neighbors that foragers gained during the end of the Pleistocene and first half of the Holocene paved the way for an agropastoral society several thousand years later. This complex issue has been addressed in the Salt Puna by focusing on the study of edible plant microfossils – starch grains and phytoliths – associated with grinding stones, knives, and projectile points found in foraging contexts dating ca. 5.5 ka, as well as very large knives and scrapers dating to ca. 1 ka (Escola et al. 2013). Residues and phytoliths akin to amaranth (*Amaranthus caudatus/A. mantegazzianus*), algarrobo (*Prosopis* sp.), walnut (*Juglans australis*), canna (*Canna edulis*), cactus (*Opuntia* sp.) and pseudocereals such as quinoa and *kañiwa* (*Chenopodium quinoa* and *Ch. pallidicaule*) and maize (*Zea mays L.*) have been identified. Although the latter originated in warmer ecological zones, quinoa was locally produced and harvested, as shown by the remains of quinoa stalks dating ca. 3.6 ka. In the Puna of Salta and the Dry Puna in Jujuy, quinoa microfossils ca. 3 ka have been identified on grinding stones. Archaeological evidence shows that quinoa was present first in the Puna and later spread to the lower valleys (Babot and Hocsman 2015; Babot et al. 2012).

Future Directions

Archaeologists working in the Argentine Puna continue to make great strides in their research by interacting with professionals in the Americas and Europe, teaching seminars, publishing papers in international journals, attending international conferences to disseminate results, and training young graduates who will become the next generation of specialists. Multidisciplinary approaches are becoming more common, as these studies have gained momentum in the last 5 years, particularly paleoenvironmental analyses that aim at understanding broad-scale environmental changes. By examining multi-proxy records – including sediment, pollen, and diatoms of alluvial deposits – in several localities, archaeologists have identified environmental conditions in the Puna that, in general, coincide with records at a macro-regional scale in the Central Andes: more humid conditions during the Early and early Mid-Holocene and an arid Mid-Holocene. Moreover, carbon isotope composition analyses of peat deposits are enabling a better understanding of the relationship between environmental and climatic variability, animal and human diet, and mobility patterns (Morales et al. 2016; Tchilinguirian and Morales 2013; Tchilinguirian et al. 2012). Finally, new lines of research are focusing on ancient DNA of archaeological Chenopodium seeds and stalks, as well as of human bones, teeth, and hair. On the one hand, it is hoped that results will provide insight regarding the process of domestication of quinoa. On the other hand, results will shed light on the prehistoric haplogroups and specific lineages of human populations that inhabited this high altitude region and lend support to either a

coastal migration along the Pacific or an inland migration within South America during the end of the Pleistocene.

Pwiti, Gilbert

Thomas Thondhlana
Institute of Archaeology, University College London, London, UK

Basic Biographical Information

A jack of two trades and master of both is a befitting statement to introduce Gilbert Pwiti. This biographic entry outlines the illustrious career of the exceptional academic and pioneer of modern archaeological and heritage management research in southern Africa and Zimbabwe in particular. Zimbabwe has enjoyed a comparatively long history of archaeological research starting from the early twentieth century. However, most of the initial archaeological investigations were done by expatriate professional archaeologists of European and American descent, including David Randall-MacIver, Gertrude Caton-Thompson, Roger Summers, Peter Garlake, Tom Huffman, and Robert Soper. It is against this background that we have to assess and appreciate the enormous contributions of Gilbert Pwiti to the archaeology and management of heritage in Zimbabwe.

Gilbert Pwiti was born in 1958 in Mazoe in the then Federation of Rhodesia and Nyasaland that comprised three British colonies, namely, Nyasaland (now Malawi), Northern Rhodesia (now Zambia), and Southern Rhodesia (now Zimbabwe). Twenty-two years later he successfully completed the Bachelor of Arts Dual Honors in History and African Languages at the University of Zimbabwe (*hereafter* UZ). At the same time Zimbabwe was emerging as a new country following a decade of protracted war against minority white regime. The new country, like any other newly independent African country, was in dire need of restoring pride by rewriting its history that was distorted by a century of British colonization. Naturally archaeology was one of the ways to rewrite the precolonial past, a period notable for

its lack of written documents. With his passion for history, Gilbert was among the first generation of indigenous historians to receive archaeological training abroad in the postcolonial period. In 1983 he left for Europe to read for an M.Phil. in Archaeology at the University of Cambridge. Upon his return from Cambridge after 2 years of training, he found himself faced with the task of setting up an archaeology unit, the first one in Zimbabwe, within the Department of History at UZ. He was instrumental in introducing archaeology and prehistory courses to undergraduate students who were majoring in History. By 1990 the first fully fledged archaeology degree program began to be offered at UZ as a result of the commitment to teaching by Gilbert Pwiti and his colleagues, Peter Garlake and Robert Soper (Pwiti 1994). Gilbert was subsequently awarded a Ph.D. in Archaeology by the University of Uppsala in 1996 for his research on the early farming communities and complex societies of northern Zimbabwe (Pwiti 1996a). In 2000 he was once again instrumental in the establishment of the Master of Arts degree in Heritage Studies at UZ. Beyond UZ Gilbert has also assisted his former colleagues and students to establish archaeology and cultural heritage degree programs at Midlands State University (MSU) and Great Zimbabwe University (GZU). Today Zimbabwe has hundreds of professional archaeologists and heritage managers practicing their trade in the country while several have been "exported" to neighboring countries.

Major Accomplishments

During the formative years of his career, he largely focused on the archaeological *terra incognita* regions that included northern Zimbabwe, and more recently he has shifted his attention to unexplored parts of eastern Zimbabwe. Prior to his investigations, archaeological research tended to be much more limited in terms of geographical coverage with most studies concentrating on Great Zimbabwe and the surrounding areas. His research in the mid-Zambezi Valley, a region perceived as marginal for agropastoral pursuits and thus neglected by archaeologists, documented the appearance of the earliest farmers in southern Africa (Pwiti 1996a). His archaeological investigations at Kadzi documented the occurrence of farming communities in the fifth century CE, at least three centuries earlier than previously assumed. The end result of his research was the revision of the cultural sequence of northern Zimbabwe together with the modification of the purported Bantu population movements that supposedly took place at the beginning of the first millennium CE. His focus on second millennium CE farming communities in the same area broadened our understanding of the complex transformation of non-stratified communities to more complex systems (Pwiti 2004). He also questioned the existence of the second wave of Bantu migrations that had been thought to have occurred at the beginning of the second millennium CE. His research findings on this issue refuted the idea that only population movement could account for the sociopolitical changes that occurred in southern Africa. These conclusions challenged racially biased migration theories that were always used to explain sociopolitical changes in African archaeology in favor of autochthonous developments resulting from changes in economy and ideology (Pwiti 2005).

His research on the archaeology of farming communities subsequently resulted in the development of a sustained interest in the management of cultural resources. He has since extensively published on the inadequacies of heritage management policies and the need to revise statutory instruments that were enacted during the colonial period which still guide the protection and preservation of cultural resources in postcolonial Africa. He initiated a number of innovative concepts that ought to be the guiding principles for heritage managers in postcolonial African countries. He was among the first scholars to advocate for the recognition of the importance of intangible aspects of heritage, reconciliation of modern and traditional heritage management approaches, and

championed community participation (Pwiti 1996b, 1997b; Pwiti and Mvenge 1996). His work on heritage management practice in southern Africa highlights how colonization alienated the colonized from their heritage physically and culturally (Pwiti and Ndoro 1999; Ndoro and Pwiti 2001). Colonial land resettlement policies and private land holding rights saw the forced removal of people from their immovable heritage, while the education system and churches were used as vehicles to make people despise their own heritage. Vast tracts of land were designated nature reserves, game sanctuaries, and commercial farms. As a result ancestral grave yards, religious centers and shrines became out of bounds since indigenous populations were denied access. It has been Gilbert's agenda to "restore lost cultural values and pride" so that the once colonized people can appreciate their own heritage and eventually participate in its management. The implementation of some of his proposed concepts particularly community participation in heritage management has not been without challenges. The recent stocktaking of heritage management practice in postcolonial Africa has highlighted a new set of challenges that come with the concepts that he prescribed initially (Chirikure and Pwiti 2008; Chirikure et al. 2010). In some cases it has proved difficult for heritage managers to identify "communities," "indigenous groups," and "traditional custodians." In principle, professionally trained heritage managers and policy makers now recognize the importance of involving traditional custodians in the management of heritage resources, but the implementation and particularly the identification of legitimate custodians is easier said than done.

Gilbert Pwiti has (co)edited and (co)authored several seminal publications that focus on a range of aspects on African archaeology and heritage management (Pwiti 1997a; Ndoro and Pwiti 2005). In 2001 he teamed up with his colleagues in East Africa to launch a publication series entitled *Studies in the African Past*. This series has since been the outlet to showcase recent and ongoing research in eastern and southern Africa. To date Gilbert Pwiti has held several administrative positions at UZ, and beyond the university he has acted as an advisor for matters of heritage management. In spite of the demands of these administrative jobs and research commitments, he has never stopped lecturing. He is an outstanding and eloquent teacher with a lot of enthusiasm in the African prehistory and heritage management. His commitment to the archaeology unit he founded at the university has seen him staying put even in the most difficult times when others went in search of greener pastures. His publications are very useful, but we should acknowledge that they will not always stand the test of time as such may one day become outdated. Having said that, it is through his contribution to the teaching and training of more archaeologists that Gilbert sows the seeds of knowledge that will last forever. He has been instrumental as a mentor of many professional archaeologists and heritage managers in Zimbabwe. Apart from UZ he has been able to share his experience as a visiting professor and external examiner at several leading archaeology institutions and departments in Africa and abroad. This international exposure has allowed him to secure funding for his students who have furthered their archaeological studies at leading archaeological institutions and departments in Africa and Europe. Through his commitment to the training of indigenous archaeologists Gilbert has shown that the economic theory of "kicking away the ladder" once one climbs to greater heights has no place in the world of academia. The present and future generations of archaeologists and heritage managers in Zimbabwe are therefore indebted to him. For his contributions and service to his country and southern Africa, it is not surprising that Gilbert Pwiti became the first professor of Archaeology in Zimbabwe. His services to global archaeology were acknowledged when he was elected the acting president of the World Archaeological Congress (1998–2000). On the final analysis of his career to date, Gilbert has demonstrated that for one to be an archaeologist, one has to be a versatile and passionate researcher, supervisor, and teacher.

Pyburn, K. Anne

K. Anne Pyburn
Indiana University, Bloomington, IN, USA

Basic Biographical Information

Anne Pyburn is Professor of Anthropology at Indiana University where she is Director of the Center for Archaeology in the Public Interest (CAPI). She is the Director of the Chau Hiix Project in Belize, Director of Community Cultural Resource Management for the Silk Road Project in Kyrgyzstan, and Director of the MATRIX Project for educational development in archaeology.

Major Accomplishments

Dr. Pyburn's interests include archaeological research ethics, heritage and globalization,

gender, early cities, the ancient Maya, and the growing emphasis on heritage and national identity in Kyrgyzstan. She is currently serving as Chair of the International Scientific Committee for the seventh meeting of the World Archaeological Congress (WAC-7).

Q

Qhapaq Ñan Program

Giancarlo Marcone and Luis Elias Lumbreras
Ministerio de Cultura del Peru, Lima, Peru

From the mid-fifteenth century of our era, the *Qhapaq Ñan* or "Great Road" was the complex road system formally used by the Incas to promote the development of their multiethnic political project that has maintained a remarkable force as an articulating element of diverse Andean peoples located in the present countries of Colombia, Ecuador, Peru, Bolivia, Chile, and Argentina. This road network was built on the roads and road systems of previous civilizations, which were integrated into a defined political project. The connection of these populations with this ancestral road network is not limited only to the memory of a glorious pre-Hispanic past but to an effective means to achieve points of encounter, exchange, and communication between regions and diverse geographies in every sense.

The Archaeological *Qhapaq Ñan*

Thanks to archaeological and historical studies, we now know that the road system of *Qhapaq Ñan* had its starting point in the place called by the Incas *Haucaypata*, where today the main square of Cusco City is located, in the southern hill range of Peru, from where a planned organizational strategy was designed for the four cardinal points of the Andean territory: *Chinchaysuyu* (north), *Collasuyu* (south), *Antisuyu* (east), and *Contisuyu* (west). It thus covered almost the entire Peruvian territory; Archaeologists such as John Hyslop (1992) have estimated its size in 25,000 kilometers or more, considering the Main Road and secondary or transverse roads. Clearly, current studies have been focused on highlighting the administrative facilities of the road network, overemphasizing the adaptive/functional component of this network. These explanations based on the emphasis of an administrative logic overshadow the recognition of other meanings linked to the presence of Inca constructions in the landscape, such as the role of the communities' perceptions over space when establishing interregional relations. The network of Inca roads or *Qhapaq Ñan* should not be understood only as an administrative network of exchange or circulation of raw materials, manufactures, and manpower at the service of the Empire but also as a way of relating to the environment.

The *Qhapaq Ñan* as Transformer of the Territory

It is now recognized that the crossing of the road through certain spaces or certain snowed peaks could have repercussions on how social relations

© Springer Nature Switzerland AG 2020
C. Smith (ed.), *Encyclopedia of Global Archaeology*,
https://doi.org/10.1007/978-3-030-30018-0

were established in the interior of group or the adjacent groups, as well as in their interactions. The location of these shrines seems to have been important or more important to the Inca society than to reach an administrative center or a *tambo* (an enclosure located next to a main road, used as a shelter and sometimes as a collection center). In this alternative view, roads are not only state administrative tools, they are also present in daily life and in the interaction of man with his environment. That is why, even when the Inca imperial administrative centers collapsed after the collapse of the *Tahuantinsuyu*, some of the functions of the road as the link between the centers and *tambos* disappeared, but the local populations continued using it, causing the road to continue fully valid, at least as an axis of movement in the Andes up to the present. This vision of a living and active *Qhapaq Ñan*, transverse to Peruvian history, is based on the incorporation of concepts such as anthropology of movement, territory, and landscape to the archaeological analysis of the road and its heritage management. Thus, the enormous potential of *Qhapaq Ñan* is evident. Being the path that links the past and its present, it allows us to move away from exclusive patrimonial schemes. Likewise, being the route that manifests the spatial diversity, it has the potential to communicate our particularities. Therefore, the management of the road as patrimonial good should aim at making it an active vehicle of development, improvement in the living standards, and social inclusion.

The *Qhapaq Ñan* Project of the Peruvian State

Since 2001, through the Supreme Decree No. 031–2001-ED and the subsequent Law No. 28260, the Peruvian Government declared preferential interest in the investigation, identification, registration, protection, conservation, and value-added of the Inca road network or *Qhapaq Ñan* throughout the national territory. That was why a National Commission was created. The Commission, from that date to the present, has been implementing the *Qhapaq Ñan* Project, which, through a series of specific projects and various activities, has been carrying out interventions in a sustained manner throughout the entire road network in the country with the purpose and following the mandate of the regulations provisions. The *Qhapaq Ñan Project* is developed by the Vice Ministry of Cultural Heritage and Cultural Industries of Peru's Ministry of Culture, and it implements actions under three strategic lines (*Qhapaq Ñan* Project's 5-year plan 2016–2020. Ministry of Culture, Lima):

1. Promote research, protection, conservation, and social use of the Inca Trail, as well as its associated cultural heritage and landscapes, in a process of agreement with the social actors involved in each area of intervention within the national territory.
2. Promote communication mechanisms, which aim, on the one hand, to build knowledge and shared action in local and regional areas in relation to the related cultural heritage and, on the other hand, to spread all aspects of *Qhapaq Ñan* in different national and international spheres.
3. Strengthen the institutional framework of the *Qhapaq Ñan* Project, within the framework of the decentralization process of the culture sector, optimizing the resources and processes in the achievement of the purposes for which it has been created.

Over the years, to the present, the *Qhapaq Ñan* Project has managed to identify and record 14,781.07 km of linear extension between the main road and secondary roads; besides, the registration of 2010 archaeological sites linked to the road and the Inca presence at national level has successfully been achieved. The results of this systematic work have constituted a database scientifically verified, rectified, and updated by specialized professionals and technical teams of field and cabinet, in order to achieve greater precision in its future use in the framework of specialized studies. (This information, open to the public, can be found now in the Ministry of Culture's web page, www.cultura.gob.pe, *Qhapaq Ñan* link.)

Contemporary Management of the Past

As has been defined above, the *Qhapaq Ñan* is a living path, part of our past and present history, therefore, its patrimonial management, imposed by national law, obliges us to take care of the path not only as a trace of the Inca past but also as an actor who has meaning and function for modern populations. That is why it is necessary to develop forms of heritage management that include people, landscapes, and material heritage. The case of the *Qhapaq Ñan* is especially interesting in this respect, since the heritage is conceptually between the local and the national (and even the international), between the rural and the urban, between the traditional and the modern, and between the preservation and the change.

The *Qhapaq Ñan* Project of the Ministry of Culture uses two concepts for the patrimonial management of the road: territorial management and social use. Territorial management is expressed by placing the path in its natural and social context, where interventions must be linked in all aspects and caring that any measure on heritage does not affect the other constituent elements of the territory. This territorial management forces us to change the conception of what the management unit should be. The program has opted for a management that is not focused on archaeological sites but in parts or segments of the road, as this allows us to plan long-term actions in an integral way, besides constituting a more adequate scale of patrimonial management to integrate the landscape and the people. In this territorial management, we consider it is very important that the rebirth of the road as a heritage does not end up dispossessing the local people of land and their own cultural manifestations, in a context where national and international forces strive to appropriate it.

The second guiding concept is that of participatory management, which we have promoted by rethinking the concept of "social use" that has been used for some years in a rather confusing way. The *Qhapaq Ñan* Project understands the social use of cultural heritage "as a dialogical and democratic process that seeks to protect, conserve and promote material and immaterial cultural assets in a participatory manner, seeking its reconstitution as a transcendent element for the sustainable development of communities" (Marcone and Ruiz 2014). Following this concept, our role as cultural managers is not to favor one group or another of social actors acting and negotiating around the *Qhapaq Ñan* but to ensure the conditions so that no group would be excluded from this negotiating space because they have no economic power or political force, as it has happened many times in the past.

In the light of these concepts, the *Qhapaq Ñan* Project proposes lines of action that make the road management participatory and facilitates its integral territorial management (Marcone and Ruiz 2014: photos 17a and 17b). These lines could be summarized in four: (1) to generate dialogue processes to recognize common interests and establish consensus, so that the populations have an active participation in decision-making; (2) to develop a participatory planning process for the development of joint actions, where local communities and local stakeholders are directly involved in the planning and execution of our actions; (3) to implement an agreed management process for sustainable development, where heritage is not an end but an element that contributes to improving the living standards of the associated populations; and (4) to generate an appropriation of the heritage returning its significance in the local area in the day-to-day.

Qhapaq Ñan as World Heritage Recognized by UNESCO

Due to its features, *Qhapaq Ñan* fulfills the requirements set by UNESCO for its recognition as a World Heritage. It presents the criterion of Exceptional Universal Value by representing a masterpiece of the human creative genius that attests an exchange of influences at an architectural, technological, landscape, and administrative level. It also provides the unique testimony of a cultural tradition or a living civilization, being an exceptional example of traditional settlement, use of natural resources, and interaction with the

environment, being directly associated with events and living traditions.

Considering all this, in May 2001, the Government of Peru took the initiative to register the *Qhapaq Ñan-Andean Main Road* on the World Heritage Tentative List. Subsequently, in 2003, representatives of Peru, Argentina, Chile, Colombia, Bolivia, and Ecuador attended meetings, first in Lima and then in Cusco, to outline the basis of the current process. Subsequently, with the same objective, meetings continued in other countries, to continue building the application file. The Candidature File was officially presented by the six countries involved in the process on the first day of February 2013 to the World Heritage Center. The Andean road system was included in the World Heritage list in June 2014. The prepared dossier consists of chapters detailing the technical characteristics of the good that it intends to nominate, such as identification of the good, description of the good, state of conservation, justification of the registration, database, legal matrix, management plan, and a voluminous cartographic atlas.

This process is unique, because it symbolizes the unity of six countries, which came together to develop a dossier. This unit is the result of intense coordination – where concepts, methodologies, and legislation of each country have been harmonized and persisted even during armed conflicts. This is a worldwide example of interregional unity and collaboration. This process is also a global milestone, since *Qhapaq Ñan* is the largest monumental asset to be presented to UNESCO to be included on the World Heritage List. Its magnitude represents a series of challenges for its management and preservation, forcing us to rethink methodologies and concepts. Thus, *Qhapaq Ñan* is called to become the model example of the concept of "Cultural Itinerary," a concept of heritage management that links monuments, landscape, and people.

Obtaining the title of World Heritage entails a series of responsibilities of the States Parties with the aim of protecting and preserving it for future generations. It also brings advantages that could benefit the following depending on the level of management:

(A) Belonging to an international community that appreciates and is interested in goods of universal value that represent a set of exceptional examples of cultural diversity and natural wealth.
(B) The nominated good acquires international recognition.
(C) Opening possibilities for the signing of international conventions for the protection and conservation of the good.
(D) It increases the flow of visitors interested in knowing the good and dynamizes the local, regional, and national economy of a country through tourism.
(E) It commits all State authorities to protect, conserve, and manage the good in a sustainable way.
(F) It allows the access to the Fund of the Humanity Heritage Conservation.
(G) It receives emergency assistance for damage caused by natural and man-made disasters.
(H) It benefits from the development and implementation of a comprehensive Management Plan that proposes adequate preservation measures as well as monitoring mechanisms.
(I) Therefore, it brings greater public awareness in favor of it and its exceptional values.

Quebec Archaeology

Christian Gates St-Pierre
Département d'anthropologie, Université de Montréal, Montreal, Canada

Introduction

With its distinctive culture, language, history, and institutions, the Province of Quebec occupies a unique position in the archaeological landscape

of Canada and North America. Within Canada, only Quebec's territory includes temperate, boreal, and arctic ecological zones, respectively home to Iroquoian, Algonquian, and Inuit cultures (Fig. 1). These indigenous peoples, along with the French and British colonists who arrived much later, had to learn to coexist through a long and difficult history, occasionally marked by political and cultural clashes. As a result of these particular conditions, archaeology as a discipline did not develop in Quebec quite like it did elsewhere on the continent.

Q

The general history of archaeology in Quebec has already been the subject of other publications (Clermont 1999, 2001; Martijn 1998). This entry emphasizes the sociopolitical and sociocultural context of the development of archaeology in the province, as well as considering contemporary issues and debates (see also Zorzin and Gates St-Pierre 2017). This short summary of Quebec archaeology is relevant in the context of an increasingly globalized, decolonized, non-hierarchical, and inclusive archaeological praxis, where regional histories and developments can inform, or even lead, discussions on more global issues. Many academics and professionals now have an interest in contrasting national and regional archaeologies. The former have become less hegemonic than before, while the latter are increasingly encouraged to expose and share their visions and experiences, their failures and successes. The contemporary organization and praxis of archaeology in other regional archaeological perspectives, as well as national and international ones, can benefit from this comparative work. Fostering this discourse is an objective shared by global organizations such as the World Archaeological Congress, as well as by many conferences and publications, including the present Encyclopedia of Global Archaeology. In such venues, local and regional archaeologies are valued, compared, and presented to a wider, global audience. Quebec is only one example of "glocalization": a regional archaeology evolving in an increasingly globalized world, yet maintaining its distinctiveness.

Inauspicious Beginnings

Although the first attested archaeological discovery in Canada took place in Bécancour in 1700 AD (Gates St-Pierre 2016: 18–20), archaeology as a profession and discipline was slow to develop in the province, leading American anthropologist Frank G. Speck to assert that "no region of such size on the continent has been less explored" (Speck 1951: 21). Before the 1960s, archaeology in Quebec consisted in either fortuitous finds by amateurs and laypeople, or projects conducted by archaeologists from various institutions outside the province. For example, when the Dawson site, a large sixteenth century Iroquoian village, was accidentally discovered in 1859 during road works near the present-day campus of McGill University (Pendergast and Trigger 1972), the discovery was reported to John W. Dawson, a geologist and Principal of what was then McGill College. Dawson, accompanied by a few members of the anglophone elite of the time, conducted further excavations, as well as collecting surface artifacts. This was one of the first archaeological rescue projects in Canada (McCaffrey and Jamieson 1992). William J. Wintemberg of the National Museum of Man in Ottawa conducted several explorations and excavations along the north shores of the St. Lawrence River Valley, from Lanoraie to Brador, during the early twentieth century. During the 1940s and 1950s, archaeologists and anthropologists such as Valerie Burger, Edward S. Rogers (Royal Ontario Museum), and Frank G. Speck (University of Pennsylvania) surveyed the boreal forest, collecting large numbers of prehistoric artifacts. William E. Taylor (National Museum of Man) pioneered archaeological research in Nunavik, the arctic region of Quebec. Gordon G. Lowther was the first archaeologist to teach that discipline in the province, at McGill University, from 1954 to 1964, when he was replaced by Bruce G. Trigger (Martijn 1998).

Over about the same time period, rural areas were also the scene of surface artifact collection and improvised, small-scale excavations by clergymen. Abbé René Lévesque was one such prominent figure in the early history of archaeology in Quebec (Lévesque 1962). In a province where education was still largely controlled by the Catholic Church, priests and abbots were among the few French-speaking people of the time who were aware of, and were interested in the archaeological past. It would take a revolution, though a "quiet" one, to give a new direction to both Quebec society and Quebec archaeology.

The Awakening

Quebec's Quiet Revolution (*Révolution tranquille*) unfolded in the 1960s as social movement aiming at modernizing and secularizing teaching in the province, as well as increasing francophone control over the province's economy and policy. Among many tangible consequences was the creation of a *ministère des Affaires culturelles* (MAC) in 1961 and a *ministère de l'Éducation* in 1964. In turn, these fostered the creation of the first department of anthropology in the province, at Université de Montréal (1961), and a second one at McGill University (1968). The MAC was very active in organizing the practice of archaeology in the province. Of particular significance was the adoption, in 1972, of both the *Loi sur les Biens culturels* (Cultural Property Act), and the *Loi sur la qualité de l'environnement* (Environmental Quality Act). These laws protect the cultural heritage of Quebec, including archaeological sites and collections. A province-wide site inventory and salvage programme followed, as well as the adoption of the *Règlement sur la recherche archéologique* (in 1973), a provincial regulation that sets the conditions and standards of conduct for archaeological research.

Many developments that were foundational to the practice of archaeology in Quebec emerged during the vibrant period of 1960s and 1970s. The first francophone association of archaeologists, the *Société d'archéologie préhistorique du Québec* (SAPQ), appeared in 1965, to be replaced by the present *Association des archéologues du Québec* (AAQ) in 1979. The province's first archaeology museum opened in Trois-Rivières in 1963. The first archaeology journals published in French included the *Cahiers d'archéologie québécoise* (1964), *Recherches amérindiennes au Québec* (1971), *Études Inuit Studies* (1977), as well as the *Paléo-Québec* (1974), *Dossiers* and *Cahiers du Patrimoine* series (1975). Archaeology was first taught at both Université du Québec à Montréal (UQAM) and Université Laval in Québec City in 1971. The academic study of archaeology at that time was inspired and influenced by Anglo-Saxon and French thinking alike.

In 1963, the provincial government nationalized the production and distribution of electricity through the Hydro-Québec public utility. Large-scale hydropower construction projects ensued, especially in the James Bay area. Those projects needed to comply with new laws mentioned above, which meant conducting salvage archaeology projects in anticipation of the huge amount of land that was to be flooded to create hydropower reservoirs. As the *Service d'archéologie et d'ethnologie* of the MAC alone could not meet the demand for surveys and excavations (Martijn 1998), this triggered the formation of the first contract firms in the domain of cultural resource management (CRM) in the 1970s. Thus, the nationalization of electricity production indirectly led to the privatization of salvage archaeology. While the nationalization of electricity was carefully planned, the privatization of salvage archaeology through CRM firms was a serendipitous development, but one that was here to stay.

Consolidation and Ideology

The 1980s and 1990s were years of consolidation and increased professionalization of archaeology as a discipline and profession: the Ostéothèque de Montréal was founded in 1982 by Quebec's first generation of zooarchaeologists; an archaeology laboratory was created at Université du Québec à Chicoutimi in 1984; the first PhDs focused on Quebec archaeology were granted in 1980s; the academic journal *Archéologiques*, the *Signes des Amériques series* and the *Cahiers d'archéologie du Célat* were launched in 1987, 1982, and 1998, respectively. A number of new museums were founded, such as the Musée québécois d'archéologie at Pointe-du-Buisson (1986), the Canadian Museum of Civilization in Gatineau (founded in 1989 as the successor of the National Museum of Man), the Pointe-à-Callière Museum in Montreal (1992), and numerous local or regional archaeology museums and interpretation centers across the province. The Laboratoire et Réserve d'archéologie du Québec and the Centre de Conservation du Québec, which together

provide artifact storage, restoration, and conservation services, were founded in 1989 in Quebec City. The ministère des Transports, the City of Montreal and the City of Quebec all hired full-time staff archaeologists, while academic and CRM projects, including field schools, were being conducted in almost every part of the province, providing field experience to countless students and young professionals.

These years of archaeological expansion had their downsides, however. It was difficult for archaeologists to explore the huge territory of the province (1,667,000 km^2), and some areas were improperly documented, and remain so to this day. Despite its professionalization, the practice of archaeology remained a commodified, precarious, and often unrewarding activity to the eyes of many practitioners, who would eventually leave archaeology for better professional horizons in other domains (Martijn 1998; Zorzin 2010). Some also lamented the lack of interest in theory among Quebec archaeologists (Dumais 1994; Martijn 1998), a situation that has not significantly improved since then (Gates St-Pierre 2009). Although AAQ meetings have always been a forum for debate, most discussions have revolved around the practice of archaeology as a profession, eschewing theoretical and reflexive debates.

Moreover, nationalistic ideology occasionally impacted archaeology, one example being the restoration of Place Royale in Quebec City's Old Town. This project began in 1967 and continued through the 1970s and 1980s, with the district being declared a UNESCO World Cultural Heritage Site in 1985. The aim of the restoration was to recreate the postulated "Golden Age" of the French Regime (1534–1760) right in the cradle of New France (Auger and Moss 2001). The archaeology of Place-Royale during the 1970s was thus entirely focused on this specific period, to the exclusion of all others; later buildings erected on Place-Royale were simply demolished or torn down. The result was a homogenized and idealized re-creation, verging towards disneyfication. A lack of knowledge about the nineteenth-century occupations of Place Royale and Old Town is a lasting consequence of this approach. It is also regrettable that such an ideologically driven project necessitated the expropriation and relocation of most of the residents who would therefore not benefit from the project, contrary to the tourists and shop owners.

Nationalism also influenced the vision and actions of the Parks Canada Agency, which was established by the Canadian federal government in 1911 as the world's first national park service. With a mandate to commemorate places of "national historic significance", Parks Canada's archaeology was clearly a "mission-oriented" enterprise (Fry 1986). The agency's archaeologists unquestionably contributed to the advancement of historical, industrial, and underwater archaeology in Quebec through large-scale projects at the Forges du Saint-Maurice, for example. However, Parks Canada also deliberately propagated a sense of national unity and identity through the historic sites it managed. Their national unity agenda developed partially as a reaction to the Quebec sovereignty movement, which advocates secession from Canada. By trying to impose its own vision of the nation's history from coast to coast, Parks Canada's agenda frequently suppressed local interests and regional perspectives on the past. This form of cultural colonialism was a way to strengthen the power of the federal government within Quebec (Craig-Dupont 2011) during a period of high political tension between the federalist and sovereignist movements. Moreover, Parks Canada's "nationalist-conservationist narrative" often impeded indigenous people's appropriation of their history and territories (Wright 2014). A more recent example of the impact of nationalism on archaeology is the 2013 renaming of the former Canadian Museum of Civilization, now the Canadian Museum of History, located in Gatineau (near Ottawa), and the reduction of its mandate to focus on national history and prehistory, to the detriment of the world-wide perspective previously employed (Aronczyk and Brady 2015).

Until recently, Parks Canada was the single largest employer of archaeologists in the country. However, the neoliberal ideology of austerity and privatization of state services carried out by the federal government during the early 2010s

resulted in the nearly total dismantling of the archaeological services at Parks Canada. Thus, all but one of the archaeologists working for Parks Canada in Quebec were suddenly and irrevocably laid off in 2012. The Quebec archaeological community thereby lost a large number of highly qualified archaeologists possessing unique and internationally recognized expertises. Moreover, many national historic sites were left without archaeologists to document, interpret, and showcase the archaeological value of these sites. Finally, all regional collections of artifacts belonging to Parks Canada are to be relocated in a single warehouse in the Ottawa area, depriving or limiting access to the archaeological heritage of Canadians in most regions of this vast country, including Indigenous peoples. All this in the name of the short-sighted, neoliberal dogma of rationalization and the ideology of centralization.

The Quebec government, sharing a similar ideology (Gattinger and Saint-Pierre 2010), adopted a disengagement policy whereby many provincial responsibilities towards the province's archaeological heritage are being transferred to towns and cities. Unfortunately, most of these lower level administrations lack the experience and financial resources necessary to act as responsible stewards of archaeological sites and collections. Likewise, the present version of the Cultural Property Act (*Loi sur le patrimoine culturel*, as revised in 2012) now allows real-estate promoters and developers to hold an archaeological permit, whereas previously these permits were only granted to qualified archaeologists. This opens the door to intervention into archaeological decision-making by actors with possible conflicts of interest, with all the possible negative outcomes that implies. It is interesting to note that while the Quebec government's stated rationale for this modification is that it will make land owners and entrepreneurs act more responsibly in their handling of archaeological sites, it does so by relegating the government's own responsibilities as steward of the province's archaeological heritage. Moreover, this is one more step towards the gradual privatization of heritage and archaeology in Quebec, with its inherent ethical and professional consequences (Zorzin 2010, 2011; Zorzin and Gates St-Pierre 2017). The situation is exacerbated by the fact that in Quebec the archaeological sites and artifacts legally belong to the owner (whether private or public) of the land where they are found (Dominique 1981), in contrast to other Canadian provinces, such as Ontario, where they are, by law, state possessions. In addition, the *ministère de la Culture et des Communications* have asserted that it no longer has any responsibility towards archaeologists, but only towards the archaeological heritage and the public. Through that ideological stand, they have abandoned, without any justification, one of the "trinity of accountabilities" adopted by most archaeologists' ethics codes around the world: accountability to the archaeological record, to the public, and to other archaeologists. Finally, while the ministry's regulation establishes minimal requirements in field archaeology, it contains no similar provisions regarding analysis and publication, which have frequently been neglected in the context of salvage or contract archaeology (Desrosiers 2017). The situation has improved in recent years, however.

Current Issues and Future Directions

Archaeology in Quebec is now a mature and diversified discipline. Despite its late emergence and its sociocultural and linguistic specificities, it is not evolving in isolation. Today's Quebec archaeologists are more connected and have a greater mobility; they increasingly obtain their degrees from foreign universities and establish collaborations with archaeologists and scientists from other disciplines and from every continent. They publish in French, English, Spanish, or other languages in international academic journals (Gates St-Pierre 2009). In 2016, the first bilingual field school in Quebec was conducted at the Nivard site in Montreal, a collaboration of archaeologists and students from McGill University and Université de Montréal. This is also illustrative of the rising rate of interuniversity collaborations, overriding linguistic obstacles and sociohistorical divides.

Bilingualism is actually one of the greatest assets of Quebec archaeology. As a phenomenon

which emerges out of necessity, it can be observed in many other regions of the world, but not so much in North America. In fact, the bilingual or trilingual advantage can also be a dilemma for many. On the one hand, there is a pressure for archaeologists, especially young academics, to publish in international journals with high impact factors. This also supports the righteous goal to share knowledge with the largest audience possible. The result is a general propensity to choose English as the preferred language of communication and dissemination. On the other hand, French-speaking archaeologists often strive to maintain and promote regional communities of archaeologists working and publishing in their native language. Moreover, if we collectively aim at a truly globalized archaeology, one that promotes diversity, multivocality, and inclusiveness, it then becomes imperative to resist the imperialism of the scientific lingua franca and to avoid homogenizing the communication styles and languages found in publications, conferences, and other dissemination activities (Gates St-Pierre 2009; Holtorf 2008).

Some of the current challenges for Quebec's archaeological community are economic. Post-boomer generations of archaeologists in Quebec and elsewhere are now facing a slowdown of archaeological activities resulting from the 2008 economic crisis and its long-lasting effects, including a shrinking job market and increasingly precarious work conditions, especially in the private sector. Many among the younger generation of archaeologists working in the CRM industry are now getting organised through an ad hoc committee that contests this status quo and asks for better working conditions: decent salaries, improved security and health protections, more stable working schedules, etc. Other challenges are more political and ethical in nature. There is a need to establish better collaborations with Quebec's First Nations and to build an archaeological praxis through which they can reappropriate their own past, and which respects their traditions, values, motivations, and interpretations. As in many other regions and countries, Native Americans living in Quebec have long been marginalized or excluded from archaeological research projects conducted on their ancestral lands to research their direct ancestors. For a long time, their past was perceived as a less interesting, nonevolving one, especially for those groups in the boreal forest (Bracewell 2015). The situation is improving, however. Today, the Cree Nation Government hires archaeologists to conduct research and salvage archaeology on the territory of Eeyou Itsche (James Bay) it administers, for example (Fig. 2). The Avataq Cultural Institute undertakes similar projects in Nunavik. Corporation Archéo-08, an archaeological nonprofit

Quebec Archaeology, Fig. 2 Archaeologist David Denton working with Cree elders from Eeyou Istchee (James Bay), in northern Quebec. (© Grand Council of the Crees)

organization working in the Abitibi-Témiscamingue region, has a long history of collaboration with members of the Anishinaabe indigenous people. Archéo-Mamu, also nonprofit, is co-managed in equal parts part by Innu and non-Native people, aiming to research, promote, and protect the archaeological heritage of both Native and White inhabitants of the North Shore of the Gulf of St. Lawrence and its estuary. Finally, an agreement was recently passed between Université Laval and the Huron-Wendat community of Wendake, near Quebec City, to develop research projects and academic programs for Huron-Wendat students in archaeology and anthropology, among other disciplines. Other institutions such as Université de Montréal have developed academic programs in First Nations Studies, which often include courses in Quebec, Arctic, or North American archaeology. Archaeologists at the Université de Montréal also have projects that are, or will be developed and managed in collaboration with Mohawk and Abenaki communities.

Despite this move towards greater collaboration between Quebec's archaeologists and indigenous peoples, opposed visions are sometimes more difficult to reconcile, especially regarding the study of human remains, the ownership of artifact collections, or the interpretation of indigenous people's ancient history (Denton and Duguay 1993; Martijn 1998). For example, archaeological narratives about the St. Lawrence Iroquoians are sometimes contested by Mohawks and Huron-Wendats, for whom the St. Lawrence Iroquoians never existed as a distinct ethnic group. Using oral traditions, they assert that St. Lawrence Iroquoians were ancestral Mohawks and/or Huron-Wendats, claiming the St. Lawrence River Valley as their ancestral territory. On the other hand, historical, linguistic, and archaeological evidence indicates that both groups originated elsewhere, in New York State and Ontario respectively, and migrated to the Montreal and Quebec City areas during the seventeenth and early eighteenth centuries AD (Tremblay 2006). Confronting, comparing, and integrating evidence derived from sources as diverse as archaeology, history, linguistics, oral traditions, traditional ecological knowledge (TEK) and genetics, will be a demanding, yet fascinating challenge to take up in the future. Better collaborations and mutual understandings will hopefully ensue.

Archaeology in Quebec is becoming more relevant not only to indigenous peoples, but also to the general public. This was one of the aims of the Archéo-Québec Network (*Réseau Archéo-Québec*) when it was founded in 1999 by a group of archaeologists interested in disseminating archaeological knowledge. The Quebec archaeological community is now benefiting from the long-term efforts of the network, and archaeology has become a topic regularly covered in the media. Archaeology Month, held in August of each year, is a highly popular event where members of the public can participate in over a hundred archaeology-related activities throughout the province (Fig. 3). The province also boasts world-class archaeology, such as the

Quebec Archaeology, Fig. 3 Public archaeology at the Droulers site, located beside a reconstructed Iroquoian village from the 15th century AD. (© Christian Gates St-Pierre)

Pointe-à-Callière Museum in Montreal, which educates visitors through high-quality exhibits and public activities. The production of outreach publications in increasing, which also contributes to making archaeology more accessible and relevant to the public (see Bélanger and Balac 2016; Pothier 2016; Tremblay 2006, for example). The *ministère de la Culture et des Communications*, the City of Montreal and other institutions are working on facilitating access to grey literature, while other administrations are now making special efforts to publish the findings resulting from CRM projects (see Bibeau et al. (2015) for a recent example). The end result is a greater public support for funding programs that document, study, protect, and showcase the archaeological heritage of the province.

Quebec archaeologists are also addressing, at a regional or national level, issues of present global significance, such as adaptations to climate change, the development of social complexity and social inequalities, human migrations, etc. (Kintigh et al. 2014). Archaeology must also become socially, environmentally, and economically sustainable for present and future generations, an important issue that is only beginning to be addressed in this province (Desrosiers 2016). Now that Quebec archaeology sits on a solid base, its future depends on its ability to embrace new interdisciplinary, theoretical, reflexive, inclusive, community-based, socially relevant, sustainable, and globalized perspectives, without losing its distinctive character. This challenge will be a great one, in every sense of the word.

Quinoa: Origins and Development

Maria C. Bruno
Anthropology & Archaeology Departments, Dickinson College, Carlisle, PA, USA

Basic Species Information

One of the indigenous staple crops of Andean South America is the pseudocereal quinoa (*Chenopodium quinoa* Willd.). It is a tall, little branched shrub that produces thousands of seeds in a large, exserted panicle (Fig. 1). There are many varieties that are primarily distinguished based on the color of both the plant and seed. Quinoa varieties range in color from white, yellow and red to purple. Taxonomists continue to debate whether it should be placed in the Chenopodiaceae or Amaranthaceae families (Kadereit et al. 2003).

Quinoa continues to be an important food in indigenous communities throughout the Andean highlands of Peru, Bolivia, and parts of Southern Colombia, Northern Chile, and Western Argentina (Fig. 2). It is a hardy crop well-adapted to dry, cold Andean climates (Risi and Galwey 1984). Recently, it has gained popularity around the world as a "superfood" because it is gluten-free and high in protein. UNESCO (General Assembly Resolution 66/221) declared in 2013 the International Year of Quinoa because of its unique heritage and potential for improving global food security. Quinoa's growing importance in modern food systems further emphasizes the need for understanding the processes by which it was domesticated and diversified in the Andes (Bazile et al. 2015).

Quinoa: Origins and Development, Fig. 1 Field of quinoa growing near Lake Titicaca, Bolivia

Major Domestication Traits

Through artificial selection by Andean hunter-gatherers – who collected, managed, and eventually cultivated wild *Chenopodium* stands – the plant, and particularly its seeds, underwent several morphological changes. Domesticated *Chenopodium quinoa* plants have larger, more-compact inflorescences than their wild counterparts, and the seeds do not easily disperse. While whole plants do not commonly preserve in the archaeological record, carbonized seeds are very common. The seed underwent several changes that archaeobotanists can observe using a combination of standard microscopy with 5–100× magnification and scanning electron microscopy (SEM) with magnifications of between 500 and 5000×. The standards for identifying differences in wild and domesticated *Chenopodium* populations were first established by researchers who studied *Chenopodium* domestication in Eastern North America (Fritz et al. 2017). Andean archaeobotanists consider a suite of traits to identify domesticated quinoa: seed diameter, seed coat thickness and texture, and margin configuration (Bruno 2006; Lopez et al. 2015). Some also examine beak prominence (Langlie et al. 2011). It appears to be a trait that varies among quinoa varieties but is not useful for differentiating wild versus domesticated species; therefore, it is not discussed in detail here.

Seed Diameter

Like other grain crops, the seeds of domesticated quinoa tend to be larger (1.0–3.0 mm) than the seeds of its wild counterparts (1.0–1.9 mm) as humans select for larger food packages. There is, however, significant overlap in diameter; thus, archaeobotanists consider other traits to determine if a prehistoric sample is a domesticated seed (Fig. 3).

Seed Coat Thickness

As mentioned above, the domesticated varieties of quinoa tend to have light colors such as white, yellow, red, and even purple, while the wild species, often referred to as *quinoa negra*, have black seeds. The lighter color of the domesticated quinoa species is due to a thin seed coat or testa (Fig. 3). The testa is very small and can only be

Quinoa: Origins and Development,
Fig. 2 Estimated past and present quinoa cultivation. (Based on Risi and Galwey 1984)

measured using SEM. Domesticated quinoa seeds have very thin testa ranging between 1.25 and 3.75 μ; in contrast, wild *quinoa negra* testa are thick, ranging between 22 and 55 μ. Archaeological quinoa can have testa thickness up to 18 μ thick, but is thinner than *quinoa negra*, which is generally >30 μ (Eisentraut 1998; Bruno and Whitehead 2003).

Seeds with a thinner testa were likely selected because they germinate more quickly and reliably. The wide range of colors and varieties may have been selected for other reasons such as taste, texture, or resistance to climatic variation (rainfall, frost, pests, etc.). Researchers are just beginning to study the morphometric differences among quinoa varieties that may shed light on these selection processes in the past (Langlie et al. 2011).

Seed Coat Texture

In addition to testa thickness, domesticated and wild quinoa are also distinguished by the patterning found on their surfaces. Like other wild species of the Cellulata section, *quinoa negra* has a reticulate seed coat patterning. This patterning is lost in the thinner-seeded domesticated seeds resulting in a smooth surface. This trait is easily recognizable under both high and low magnification.

Margin Configuration

Examination of the cross section of seeds reveals differences in overall shape. Wild seeds tend to be biconvex, while domesticated seeds are more rounded to truncate. With a thinner testa, the rounded shape of the perisperm and radical are more prominent (Fig. 3).

Quinoa: Origins and Development, Fig. 3 *Chenopodium* seed morphology, margin configuration forms, and an SEM image of a modern quinoa seed. Note the smooth seed coat surface and very thin testa peeling back near the beak. (Based on Bruno 2008)

Timing and Tracking Domestication

The history of quinoa's domestication is still being determined through a combination of botanical, genetic, and archaeological approaches.

Genetic Evidence

The wild progenitor of quinoa has not yet been definitively identified, but recent genetic studies are providing important advances (Bazile et al. 2014; Fritz et al. 2017). The most commonly recognized wild *quinoa negra* species associated with the crop are *Chenopodium quinoa* var. *melanospermum* Hunziker and *C. quinoa* spp. *milleanum* Aellen. They share the same distribution as quinoa but are not the progenitors. Rather, these are companion weeds that evolved alongside the domesticate. The mostly likely progenitor is another black-seeded, wild species *Chenopodium hircinum* Schrader, which today is distributed along the eastern slopes of the Andes, valleys of Paraguay, Uruguay, and Argentina (Wilson 1990). Recent sequencing suggests that two ecotypes of quinoa, one highland and one coastal, were independently domesticated from *C. hircinum* (Jarvis et al. 2017). Further work is needed, however, to clarify this and archaeological investigations are key.

Archaeological Evidence

Over the past 20 years, improved recovery methods for archaeological plant remains have added to our knowledge of when, where, and in what social context quinoa may have been

domesticated. Chenopod remains have been recovered from sites throughout the Andes associated with contexts as early as 6000 BC (see Planella et al. 2014 for a thorough review). The ideal protocol for documenting domesticated quinoa specimens is via SEM analysis of their morphology, as described above, coupled with direct AMS radiocarbon dating of seeds with domesticated traits.

SEM studies have been conducted on samples from central Peru (Panalauca and Panaca Caves), the Lake Titicaca basin (Taraco Peninsula, Quelcatani Cave, Jiskairumoko), Southern Bolivia (La Barca), and Central Chile (El Plomo). The seeds from the central Peruvian caves have associated dates of about 3000 BC. Direct dates from the sites in the Lake Titicaca basin all cluster around 1500 BC. Direct dates on quinoa identified with light microscopy in Central Chile have dates of approximately 1000 BC (Planella et al. 2005). In the Ñanchoc Valley of Northern Peru, researchers have identified quinoa seeds with light microscopy that are associated with a house floor containing wood charcoal radiocarbon dated to between 6000 and 5500 BC (Dillehay et al. 2007). It is important to note that the specimens from Quelcatani Cave had associated dates of around 3000 BC, but directly dated seeds from the same contexts were younger (Eisentraut 1998). This difference highlights the importance of direct AMS dating since these small seeds can readily move vertically through the profile via postdepositional processes. Given the available information, it is clear that domesticated quinoa was being cultivated by 1500 BC, in what is known as the Early Formative period, the phase associated with the earliest farmers of the south-central Andean regions; however, it is likely that the process of domestication began earlier, with a conservative estimate around 3000 BC but possibly as early as 6000 BC.

It is hypothesized that the process of domesticating quinoa began in the Late Archaic period possibly by early camelid pastoralists in the central or south-central highlands. Chenopods are quite common in disturbed habitats and may have been particularly adapted to the camps and corrals being created by seminomadic foraging groups. Quinoa seeds have been found in both modern and archaeological camelid dung samples suggesting a coevolutionary relationship between this crop, camelids, and humans (Kuznar 1993). Continued efforts to recover, document, and date sites spanning the Late Archaic-Early Formative transition are essential to furthering our understanding of the domestication of this important Andean staple.

Quiroga, Adán

Alejandro F. Haber
Escuela de Arqueología, Universidad Nacional de Catamarca & Consejo Nacional de Investigaciones Científicas y Técnicas, Catamarca, Argentina

Basic Biographical Information

Adán Quiroga (San Juan 1863–Buenos Aires 1904) died at the age of 41, without having assumed the position of Sub-Secretary of the Interior Ministry of the Argentine Republic for which he had been appointed. He had previously held various positions in the Judiciary and had been the mayor of San Fernando del Valle de Catamarca. A trained lawyer (Ph.D. in law with a thesis on *Crime and Punishment*, 1887, University of Córdoba) and poet (*Flowers of the Air*, 1893), Quiroga was known for his studies on archaeology, history, and *Calchaquí* folklore (*Calchaquí*, 1897, *The Cross in America* (Quiroga 2004 [1901]), and *Calchaquí Folklore*, 1897 (Quiroga 1992),are his major works). He lived in a time when these disciplines were being formed; there were no clear boundaries among them, and their respective objects and methods were being defined. Quiroga participated in formative discussions of archaeology in Argentina with original positions and different proposals. The discipline, once formed and institutionalized, forgot him. This short biographical note, which brings him back, is also a reconstruction of his oblivion.

Major Accomplishments

In the last quarter of the nineteenth century, the Argentine national state was consolidating, in a process that was marked by the construction of a political and cultural hegemony of elites linked to foreign trade, over the enormous mass of southern European immigrants. The native inhabitants of the ancient provinces of the territory's interior inherited from the Spanish Empire, indigenous populations of the Chaco, the Pampas and

Patagonia (which had been defeated by the army, massacred, dispossessed from their lands, and confined to reservations), and the yearning for autonomous development of the weaker neighboring countries (which, as in the case of the Republic of Paraguay, were the object of genocide by the armies of the Triple Alliance formed by Argentina, Brazil, and Uruguay). As the core of the nationality construction policy, free, basic, general, and state education spread over the whole country becoming a real hegemonic citizenship production machine. In turn, the elites devoted huge efforts to the demarcation of a canonical historiography of Argentina. General Bartolomé Mitre, for example, was the leader of Buenos Aires' elite, commanded troops against the indigenous and against Paraguay, and was one of the leading historians; thus, he was a history protagonist performing historical deeds and writing about them.

Joaquín, Quiroga's father, was appointed Federal Judge in Catamarca by Mitre, and Adán accompanied the Mitrist party all through his life. However, his texts on archaeology and history, and his positions regarding the indigenous, were very different from what the Mitrist canon sought to establish. Bartolomé Mitre himself acknowledges his book *The Cross in America* with a laconic appreciation and a critique of Quiroga's elaborate and passionate prose.

To Quiroga, the Calchaquíes, protagonists of armed resistance to European conquest for nearly a century and a half, were worthy of admiration rather than condemnation or stigma. Quiroga proposed an Argentine nationalism that would seek its basis in the history of resistance that the Calchaquíes led for the love for their land, choosing death when they were defeated by the Spanish military superiority. To Quiroga, the "Calchaquí epic" was the emotional mobilizing force for the feelings of the fatherland; in this, he was clearly different from the Europeanized elite, which did not hesitate in pedagogically focusing on European history at the moment of shaping the new citizenship. In the same way that Indigenism would later propose in Mexico, to Quiroga, archaeology had the value of providing a national epic. At the same time, other leading academics proposed that archaeology should be limited to recover, preserve, and classify remains and to display them in museums, so that citizens would be educated about how the original inhabitants "that became extinct in this land" had been like (as Francisco Moreno expressed). In Argentine archaeology, one of the oldest institutionalization in the Americas, positions such as Quiroga's were discarded and forgotten, and positivist proposals, like Moreno's, prevailed.

Quiroga's archaeology was interested in the interpretation of symbols in rock art and ceramics, which referred to Calchaquí deities of rain and storm, wind and earth. Geography imprinted its most remarkable characters in the town: the language, the gods, symbols, and the Calchaquí's personality were definitely influenced by the landscape. There were no ruptures between the creators of the great artistic and architectural works discovered by archaeology and the Calchaquíes of the epic resistance to the conquest. But Quiroga was not, however, an advocate for the rights of their descendants. He regarded the indigenous as minors, not punishable and deserving protection. Their history had epic value for the whole nationality, but there was no continuity between their history of resistance appraisal and their rights' restoration.

Quiroga moved away from both his Hispanist contemporaries, who valued the conquest and eluded its traumatic effects, and from positivists, who valued the indigenous only as a scientific object to classify and describe. Notwithstanding, Quiroga's indigenous nationalism was not offered in opposition to liberal hegemonic projects. He himself was a notorious politician and a Mitrist intellectual, who, at the same time that he offered alternative content for the national citizenship construction project, did not question the hegemonic sense of that project.

In Quiroga's project, archaeology acquired a very relevant and different position from that his contemporaries had relegated it. To Hispanists it was a lesser form of entertainment dealing with history without indigenous interest, whereas for positivists, archaeology was a discipline cut according to natural history model, concerned with the classification and description of extinct races' remains. Quiroga's archaeology made in advance a project which would acquire

physiognomy decades later in Indigenism – notably the case of Mexico. But Argentina's cultural and political winds, whose Europeanized elite had already committed cultural decisions, were unfavorable to indigenous nationalism. Ricardo Rojas resumed Quiroga's legacy posthumously, but the influence of his work was progressively diluted. Quiroga's work and that of his contemporary scholars from the country's interior (Lafone Quevedo, the first Ambrosetti, Toscano, etc., encompassed as "historian philologists") were excluded from the pantheon of archaeology and anthropology classics by disciplinary historiographies. It was not until the 1990s that texts began to appear returning to Quiroga, awakening interest in his work and life.

Quiroga is a pioneer forgotten by Argentine disciplinary historiography, in itself marginal to historiographical narrative hegemonized by European authors. This biographical note on Adán Quiroga cannot end without stressing the contextual bias of the ways in which the discipline is self-narrated. The narratives of the past seem to have as many voices as silences.

Race in Archaeology

Charles E. Orser Jr.
Department of Anthropology, New York State Museum, Albany, NY, USA

Introduction

The explicit archaeological interest in race as a topic of inquiry only developed in the 1990s. Before this, but only beginning in the 1980s, many historical archaeologists investigated ethnicity rather than race, seeking to develop ways to use excavated artifact assemblages to identify members of historically known ethnic groups. The goal of much of this research was to correlate specific objects or kinds of objects with certain peoples. Accordingly, for example, many archaeologists equated white clay smoking pipes decorated with shamrocks with Irish men and women. By the 1990s, many historical archaeologists had decided that this sort of easy correlation neither matched the complexities of daily life nor reflected the ways in which perceived personal characteristics created social hierarchies. As a result, some archaeologists began to think explicitly about race rather than ethnicity as a focus of examination.

Definition

Diverse studies by anthropologists have proven that only one human race exists. The physical variations apparent in the world's peoples result from myriad genetic adaptations rather than the presence of true races. The biological fallacy of race, however, does not mean that racial theory has not been a continual force in modern history or that the perception of race has not had consequences, as more powerful groups have used their ideas about racial difference to cement their authority and power. The appearance and application of racial theory has meant that people identified as belonging to an inferior "race" could be justifiably denigrating and discriminated against. People seeking to create or maintain strict social hierarchies used the pseudo-science of racial theory to reinforce their claims of inferiority and superiority, claims that placed them at the top and those they despised at the bottom.

The attribution of racial designation is usually a byproduct of relations of power, and so many scholars find it useful to speak of "racialization" rather than race per se. Racialization is a process of "assigning men and women to essentialist groups, based upon physical appearance or some other readily identifiable characteristics, that

© Springer Nature Switzerland AG 2020
C. Smith (ed.), *Encyclopedia of Global Archaeology*,
https://doi.org/10.1007/978-3-030-30018-0

allow them to be perceived as biologically inferior or socially unequal" (Miles 1989: 73). This means that people in power can use cultural elements – patterns of dress, language, dialect, religious belief – to assign whole groups of people to a inferior "race" in addition to, or even exclusive of, their physical appearance. Nonetheless, much racial theory rests on physical characteristics that may be real or imagined.

The racial assignment that results from the process of racialization comes from outside the group being so designated. Racialization allows those classified as members of a specific "race" to be held in contempt by members of the defining group. Those creating and enforcing the classification may believe that their system reflects biological reality, when in truth racialization results from the mere perception of biological reality without genetic substance. The establishment of a social hierarchy is the practical outcome of the process of racialization because racialization creates superior and inferior "races." The creation of races, however, is based upon historically relevant criteria. Racial assignment at one point in history may be based on skin color, but at another time – but in the same setting – the assignment may rest on cultural tradition. In other cases, it may be based on both.

Unlike race, ethnicity – the assignment of ethnic affiliation – is an internal designation, meaning that people in an ethnic group self-identify as belonging to that group. The presence of ethnic groups within a society need not create a social hierarchy. Rather, the various ethnic groups can be viewed as simply working to maintain their own self-contained traditions, customs, and habits based on genealogy.

An ethnic group can be assigned a racial categorization. Most of the immigrant groups that traveled to the United States in the nineteenth century underwent the process of racialization at some point in their collective history. In the late nineteenth century, Italian immigrants faced the same denigration and discrimination that many Irish immigrants had experienced a few decades earlier. Later, at the beginning of the twentieth century, Eastern Europeans faced similar situations and many Mexican immigrants confront the process today.

The process of dividing peoples into disparate groups has occurred throughout human history, but historians who have examined racialization generally agree that its strongest expressions correspond with European global expansion and the rise of the worldwide reach of capitalist economics. As such, "Race is one of the central conceptual inventions of modernity" (Goldberg 1993: 3). At the very least, the subject of race is unavoidable in the United States, South Africa, and other nations where the perceived racial differences between peoples have had a long, antagonistic, and often violent history.

Our vantage point from the early twenty-first century makes it clear that the modern-world historical archaeology is the proper intellectual site from which an archaeological understanding of the racialization process must come. The subject is too important to believe otherwise.

Key Issues and Future Directions

One of the key issues in the archaeological investigation of race rests upon the identification of the material characteristics of racial assignment. Scholars from almost every discipline in the humanities and the social sciences have studied race from many theoretical perspectives using various sets of empirical evidence. The breadth of their studies reveals the complexities of race as a historical element, but they generally shed little or no light on the materiality of racial identification. As a result, archaeologists face significant challenges when attempting to observe the materiality of race in archaeological deposits and artifact collections. The historical mutability of race is a compounding problem. People racialized in one epoch may not be racialized (or may be racialized differently) in another epoch. For example, plantation owners living during in the United States' earliest colonial era often distinguished between "Negroes" and "Christians." This system of designation, which racialized the enslaved as non-Christian and inferior and the free as

Christian and superior, was relevant when the proportion of Christianized slaves was small. As the number of enslaved men and women who had adopted some form of Christianity grew, the old system of racial separation was no longer applicable. As a result, the designations "white" and "black" became more relevant as racial descriptors. From an archaeological standpoint, an archaeologist investigating racialization in colonial America would have to understand the historical mutability of racialization and work to devise ways to perceive its many permutations through time. This is a decidedly difficult project, but its intricacy does not negate the need for sustained archaeological analysis. On the contrary, the persistence of racial categorizations through time mandates serious archaeological examination.

Many ways undoubtedly exist to examine the historical characteristics of racialization using archaeological methods and perspectives. The ways to investigate the racialization process will certainly grow as increasing numbers of historical archaeologists decide to focus on its many historical dimensions. An approach that now appears to offer interpretive promise involves three related elements: the understanding of modern-era artifacts as commodities, the role that spatial practice plays in signaling racial affiliation, and the interaction between commodities and place.

Commodities are things created specifically for exchange. Commodities have assumed an increasing role in most people's lives since about 1500 CE, to the extent that most of us today purchase everything we use. Most of the world's peoples no long make their own material possessions but instead purchase them from commercial retailers and merchants. Historical archaeologists have long appreciated the importance of viewing modern-era artifacts as commodities and considerable literature exists. Regarding race specifically, archaeological analysis has demonstrated the complex linkage that occurs between racial categorization and the availability of commodities through time (e.g., Mullins 1999). Studies such as these, albeit complicated and necessarily site specific, indicate that racialized consumers could combine their need for physical things with a desire to make symbolic statements about their right to personal possessions. Within this perspective, the act of purchasing commodities is simultaneously perceived as an economic imperative and a political statement. Thus, the ownership of a toothbrush might be seen as representing the simple need of dental hygiene combined with an overt statement that by owning a toothbrush, a person racialized as inferior has the same right to hygiene as someone at the top of the racial hierarchy.

Spatial practice refers to the ways in which a particular social setting configures and promotes space both as a physical reality and as the ways in which humans manipulate, use, and recreate life and social relations within physical reality (Lefebvre 1991). Spatial practice thus includes the layouts of towns, villages, houses, rooms, roads, lanes, pathways, and everything else in the built and natural environments and the ways in which residents and visitors use and perceive them. Spatial practice is culture specific: Each culture understands its own space and perceives it as right and proper. Thus, for example, it was customary for medieval Roman Catholics to situate their cathedrals in highly visible, prominent locations because such placement was proper.

Like commodities, spatial practice can have a racialized character. The most obvious expression of racialized spatial practice can be observed in the physical segregation of people of color, immigrants, and others deemed inferior in less-than-desirable settlement areas. For example, mid-nineteenth century Irish immigrants and other financially disadvantaged people in the United States were usually relegated to flood-prone and overcrowded urban zones because they were deemed inferior by society's elite rulers. Spatial segregation is a physical reminder that space is entwined with the relations of power that are created and enforced within a society.

Archaeologists can gain insights into the presence and operation of racialization in particular social environments by combining the analysis of commodities with their spatial appearance. An artifact collection by itself may not be especially expressive of racial assignment, but it may

become meaningful when combined with its place of discovery. In other words, the presence and absence of certain commodities in only one place in a settlement may relate to the way in which people in that environment were racialized. The distribution of commodities within a complex society, such as nineteenth-century America or England will also reflect class distinctions. At present, the relationships between race and class – and their archaeological interpretation – have yet to be worked out to the satisfaction of most researchers, and future historical archaeologists will undoubtedly follow this important line of investigation in years to come.

Introduction

Radiocarbon (^{14}C) dating is an isotopic or nuclear decay method which can determine an age for once-living organic materials. The technique provides a common chronometric time scale of worldwide applicability on a routine basis in the age range from ~250 to 300 years to between 50,000 and 60,000 years. With isotopic enrichment and larger sample sizes, ages up to 75,000 years have been measured. Also, in some limited situations, ages less than ~250–300 years can be obtained (Taylor 2001; Taylor and Bar-Yosef 2014).

Radiocarbon measurements can be obtained on a wide spectrum of once-living carbon-containing samples including charcoal, wood, marine shell, and bone. For sample sizes of between 1 and 10 g of carbon, conventional decay or beta counting can be employed. Decay counting technology can be employed to measure ^{14}C concentrations by measuring ^{14}C decay events in samples and comparing those count rates with those of known ^{14}C age standards. Accelerator mass spectrometry (AMS) direct counting technology permits ^{14}C measurements to be obtained routinely on much smaller size samples. For example, samples sizes of 0.5–1 mg of carbon – and with additional effort on as little as 20 μg of carbon – can be measured. For details of how decay and AMS counting technologies are used to measure natural levels of ^{14}C in samples, see Taylor and Bar-Yosef 2014: Chapter 4.

The ^{14}C technique is widely viewed as the geochronological "gold standard" from the perspective of its potential ability to provide generally accurate and relatively precise chronometric age assignments for terminal late Pleistocene and Holocene organics (Pollard 2009). It was developed at the University of Chicago (USA) immediately following World War II by Willard F. Libby (1908–1980) and his collaborators James R. Arnold (1923–2012) and Ernest C. Anderson (1920–2013). Libby received the Nobel Prize in chemistry in 1960 for the development of the method (Taylor 2014).

Basics

Carbon-containing compounds in a wide variety of forms are distributed throughout the earth's atmospheric, terrestrial, and hydrological (primarily marine) environments**.** These compounds are cycled through various exchanging carbon reservoirs on different time scales by a variety of physical or chemical mechanisms. These carbon cycle processes are dominated by the operation of two major intersecting and interacting physical and geochemical systems.

The first involves the cycling of various chemical species – including dissolved inorganic carbon (DIC) in the form of carbon dioxide, carbonates, bicarbonates, and dissolved and particulate organic carbon (DOC) – primarily between the oceans and atmosphere. The second involves photosynthetic cycles utilizing several complex biochemical pathways involving the fixation of atmospheric carbon dioxide (CO_2) in plant materials, an incorporation of a small portion of plant biomass into animal tissue, and subsequent decomposition with the release of carbon dioxide (CO_2) and methane (CH_4) back into the atmosphere. Various chemical and physical processes including the deposition of carbonates in terrestrial and oceanic sediments and volcanic activity are also involved in the operation of the carbon cycle on much longer geologic time scales (Trumbore 2000; Schuur et al. 2016).

Carbon which becomes an active part of the earth's carbon cycles contains three *naturally occurring* isotopes, two of which are stable (^{12}C, ^{13}C) and one (^{14}C) which is, at the nuclear level, naturally unstable or radioactive. The natural radioactive isotope of carbon, or *radiocarbon*, decays with a half-life of ~5700 years. This half-life is significantly in excess of what would be expected from a comparison with isotopes with similar decay energy characteristics (Currie 2004).

The basis of the use of ^{14}C as a dating isotope is illustrated in Fig. 1 in terms of its *production*, *distribution*, and *decay*. The production of natural ^{14}C is a secondary effect of cosmic-ray interactions with the nuclei of atmospheric gas molecules. Primary cosmic rays are mostly composed of protons (hydrogen nuclei) and helium nuclei which have been accelerated to extremely high energies in intergalactic space. Because they are charged particles, many are deflected by the various components of the magnetic field of our sun and then by the dipole magnetic field of our planet. However, a small percentage of these particles, many of which continue to possess very high energies, reach the top of the earth's atmosphere. These primary particles produce a cascade of secondary particles. Collisions of both primary and secondary particles in the stratosphere with the nuclei of atmospheric gas molecules yield a range of what are termed spallation products which include free neutrons.

These free neutrons continue to interact with other particles losing energy in the process. As these particles reach appropriate energies, they can react with the nucleus of ^{14}N to form ^{14}C. This natural cosmogenic (cosmic-ray formed) ^{14}C is then rapidly oxidized by OH^- (hydroxide ion), initially to form mostly molecules of ^{14}CO (carbon monoxide), and then rapidly, these ^{14}CO molecules are, in turn, oxidized to $^{14}CO_2$ (carbon dioxide). Even though ^{14}C production at the geomagnetic poles is about five times that at the geomagnetic equator, cosmic-ray produced ^{14}C becomes generally well-mixed by the time ^{14}C-tagged CO_2 molecules reach the planetary surface and become incorporated into various forms of terrestrial biota or in the surface of the world's oceans (Cook et al. 2010).

Radiocarbon Dating in Archaeology, Fig. 1 Radiocarbon dating model: production, distribution, and decay of ^{14}C (Source: Taken from Fig. 1.1 in Taylor and Bar-Yosef 2014. Graphics by Annett Baermer, Max-Planck Institute for Biogeochemistry, Jena, Germany, through the kind assistance of the Direct, Susan Trumbore)

Because oceans comprise almost three-quarters of the earth's surface, the largest percentage of ^{14}C is found in marine environments as dissolved inorganic carbonates (DIC) such as CO_2, or in the form of carbonates or bicarbonates. The majority of this marine ^{14}C is found in the deeper parts of the world's oceans. A relatively small percentage of the earth's ^{14}C inventory becomes part of the terrestrial biosphere, first by being incorporated into plant biomass by means of several photosynthetic pathways, then into organisms which depend on various plant communities for food, and then up the entire food chain. Thus all terrestrial living plant and animal communities, which are, directly or indirectly, dependent on plants as a food resource, are tagged with ^{14}C (Usoskin and Kromer 2005).

While individual ^{14}C atoms will decay back into ^{14}N, in living organisms they are continually being replaced through the intake of plant or animal biomass and the physiological processing of this biomass. These metabolic processes in most *living* terrestrial organisms maintain the ^{14}C content in *approximate* equilibrium with atmospheric ^{14}C concentrations. However, once metabolic processes cease, as, for example, because of the death of a plant or animal, the amount of ^{14}C begins to decrease in that organism by negative beta (β^-) decay at a rate characterized by its decay constant or half-life.

The half-life ($t_{½}$) of any radioactive isotope expresses the time interval during which that isotope will decrease by a one-half or 50%. For every subsequent half-life interval, its concentration will

decrease by a factor of 2. In large part because of the very high energies involved in binding atomic nuclei together, the rate of decay of radioactive isotopes are highly stable and, with relatively rare exceptions (e.g., at most, a few percent variations for electron-capture mechanisms), cannot be altered by ordinary physical or chemical processes operating in any natural environment which exists on our planet. Since ^{14}C exhibits a half-life of ~5700 years, the amount of ^{14}C contained in a carbon-containing sample will decrease by 50% during every approximately 5700 year interval following its withdrawal from an active carbon reservoir as at death, unless one or more contaminating process causes carbon-containing compounds exhibiting different ^{14}C concentrations to be added to the sample matrix.

If all of the assumptions of the ^{14}C dating model as summarized in the next section are fulfilled for a given organic sample, a measurement of its residual ^{14}C concentration can be used to infer an accurate age for that sample. However, there are many factors that can impinge on the ^{14}C activity measured in a carbonaceous sample and thus the degree to which that ^{14}C concentration can be used directly to infer accurately and precisely the age of that sample (Taylor 2001; Taylor and Bar-Yosef 2014).

Assumptions

The ^{14}C age of a given sample is inferred primarily based on a measurement of its residual ^{14}C content. To be able to infer an accurate age based on that measurement at a useful level of precision, a set of major assumptions must hold within relatively narrow limits. These assumptions can be briefly summarized as follows (Stuiver and Polach 1977):

1. The concentration of ^{14}C in each carbon reservoir has remained constant at least over the last 100,000 years.
2. Complete and rapid mixing of ^{14}C throughout the various carbon reservoirs is achieved on a world-wide basis on a time scale of less than a few decades.
3. Carbon isotope ratios in samples have not been altered except by ^{14}C decay since these sample materials ceased to be an active part of one of the carbon reservoirs, as at the inactivation of metabolic or physiological processes, i.e., as at the death of an organism.
4. The half-life of ^{14}C is accurately known to an appropriate level of precision.
5. Natural levels of ^{14}C can be accurately measured to appropriate levels of precision.

An additional requirement for a critical utilization of the ^{14}C method is that there is a firmly documented and explicit physical contextual relationship established between a well-characterized organic sample whose ^{14}C concentration is to be measured and some specific event or phenomenon to be dated. The various factors involved in causing violations of these assumptions to varying degrees are the subject of continuing study by ^{14}C researchers. Satisfactory fulfillments of contextual requirements are in the hands of field archaeologists and geologists collecting and submitting samples for ^{14}C measurement.

Accuracy and Precision

In this discussion, *accuracy* refers to the process of obtaining a valid or correct age while *precision* refers to the degree of uncertainty within which a given value is expressed. In ^{14}C dating studies, what might be considered as an *overall* level of accuracy and precision for a given sample depends on a range of factors. It needs to be emphasized that the *measurement precision*, which is typically based primarily on measurement or counting statistics, should be regarded as providing the basis of defining a *minimum* age interval associated with that single sample. This is the "±" value that is associated with most published ^{14}C age expressions.

By international agreement among ^{14}C dating researchers, the "±" expression is cited at the level of $\pm 1\sigma$, where σ is an abbreviation of "sigma." This expression is derived from the fact

that any *measurement* of ^{14}C concentrations must take into consideration well-understood statistical concepts. This statistically based information is expressed in a standardized format in terms of sigma range values. For a brief review of what statistical concepts and information are encoded in sigma values, please refer to Taylor and Bar-Yosef 2014: 144–149.

A realistic estimate of the *overall* accuracy and precision of *individual* ^{14}C values involves a consideration of the interaction of multiple factors. When the entire range of relevant data is evaluated critically, a review of these factors often results in increasing the age range that should be cited with a given ^{14}C value and thus decreasing its overall *effective* precision**.**

One cannot over emphasize the importance of keeping the entire range of relevant variables in mind if one wishes to evaluate critically any single or suite of ^{14}C age estimates to define the effective accuracy and precision of one or more ^{14}C age determinations. Such a consideration highlights the value of duplicate and multiple ^{14}C determinations to increase the quality of ^{14}C evidence used to provide a valid chronometric temporal assignment for a given feature, stratigraphic level, artifact or cultural context.

Calibrated Radiocarbon Ages

A *calibrated radiocarbon age* takes into consideration the observation that ^{14}C activity in living or zero age organisms *on a worldwide basis* have not remained constant. Assumption 1 listed above has been demonstrated to have been violated to varying degrees over almost the entire ^{14}C time scale. Fortunately, the magnitude of the effects of such violations has been measured and appropriate measures can be taken to mitigate their effects by a process referred to as *calibration.*

The offsets between ^{14}C time and true solar or calendar time are sometimes referred to as representing *secular variation* in the ^{14}C time scale (Suess 1965). These offsets are viewed as being composed of two major components: long-term or major trends and shorter-term higher frequency offsets. The shorter-term perturbations are often referred to as de Vries effects, referring to the Dutch scientist, Hessel de Vries (1916–1959), who was one of the first to focus attention on them. The shorter-term perturbations are also sometimes referred to as "wiggles" or "warps" in the ^{14}C time scale.

The long-term variations in ^{14}C concentrations have been determined to have been caused primarily by changes in the intensity of the earth's dipole magnetic field. The primary causes of the shorter-term de Vries effects have been traced to changes in components of the sun's magnetic field together with variations in various carbon cycle parameters such as alternations in exchange rates between carbon reservoirs.

Because of these various offsets, "radiocarbon years," as expressed in conventional ^{14}C age expressions, and solar years – "real time" – are not of equal duration for most periods. Various terms for "real" time (e.g., solar, sidereal, calendar, or calibrated time) have tended to have been used interchangeably. While in this discussion we will use "calendar" or "calibrated" to designate "real time," some have argued that the term "solar" years would be more appropriate, since, strictly speaking, there are and have been various types of calendars in use, not all of which used solar years as the basis of recording the passage of time (Stuiver and Suess 1966).

Calibrated ^{14}C values were initially obtained by consulting tables or plots of relationships between ^{14}C and dendrochronologically (tree-ring) dated samples to determine the amount of offset between ^{14}C and calendar time for different periods. With the increasing precision of the calibration datasets, initially for the Holocene and now increasingly for the terminal Late Pleistocene as well, together with the widespread availability of microcomputers and the Internet, a number of computer/web site-based approaches to the calibration process are now available.

Figure 2 is a plot of the offset (in years) between calendar time and ^{14}C time for the period from 0 to 15,000 calendar years using the

Radiocarbon Dating in Archaeology, Fig. 2 Amount of deviation (in years) between ^{14}C ages and calibration sample ages taken from IntCal13 for the period: 0–15,000 cal BP (Reimer et al. 2013). The area enclosed in the lower left quadrant of the figure represents the time period documented by the first comprehensive comparison of ages tree-ring-dated and ^{14}C date wood samples from the Bristlecone pine published in 1970 (Suess 1970). The dotted line presents the expectation of a decrease in the amount of ^{14}C/tree-ring offset. The remainder of the comparison data from 8000 to 15,000 BP years represents that results of the expanded tree-ring/^{14}C comparisons and other data obtained from non-tree-ring-based temporal proxy data incorporated into the internationally agreed upon calibration data sets such as IntCal13. See text for explanation (Source: Taken from Taylor and Bar-Yosef 2014, Fig. 2.9. Original plot provided by PF Reimer and R. Reimer, Queen's University Belfast, personal communication, 2013)

currently (2018) internationally accepted calibration dataset referred to as IntCal13 (Reimer et al. 2013). This plot summarizes the evolution of understandings of the magnitude of the offsets between ^{14}C and calendar time. The first lengthy data set used to calibrate ^{14}C ages employed a series of tree-ring-dated wood samples from the Bristlecone pines from the White Mountains of east central California. The lower-left quadrant of this figure represents the plot of the relationship between the ages assigned on the basis of ^{14}C measurements and that obtained on the basis of dendrochronology on the White Mountains Bristlecone pine samples (Suess 1970). The assumption is that the ages obtained from dendrochonological study will provide the "true" or calendar ages of each annual segment of the sequence of tree-ring wood samples.

That plot revealed that the main trend ^{14}C values obtained on tree-ring-dated wood for about the last 2500 years was generally stable with de Vries deviations varying offset values during this period by a few hundred years. For a short period of time during that period, ^{14}C values were up a century or so "too old" with regard to "real time." However, focusing on the longer term

variations, the data points could be viewed as clustering around the "0" ^{14}C age offset.

However, between about 2500 years before present (BP) and about 7500 years BP, there was a continuous general increase in the offset values. By 7500 years BP, the tree-ring ages/^{14}C ages offset values based on the Bristlecone pine samples indicated that ^{14}C age values were about 1000 years *too young* with regard to calendar dates. At that point in the plot and lasting from about 7500 to 8500 years BP, the amount of offset slightly decreased. On the basis of these results, during the early 1970s, there was a hopeful expectation among some researchers that the magnitude of the tree-ring-based/^{14}C-based age offsets would decrease when additional tree-ring-dated wood became available on which ^{14}C measurements could be made. This expectation is represented by the dotted line reflecting the projected anticipated decrease in the offsets values.

Regretfully for these expectations, beginning about 8500 years BP, additional tree-ring-based calibration data documented that the magnitude of the offset values between ^{14}C and calendar time resumed their steady increase so that at about 12,500 years BP, the offset value stood at about 2000 years. This meant that, by this time, ^{14}C values were about 2000 years *too young*. From about 8500 years BP to about 12,550 years BP, the offset values were calculated based on multiple segments of dendrochronologically (tree-ring) dated species of wood primarily from German pines and oaks as well as on oak samples from the Netherlands and Ireland. The interval from 12,550 to 15,000 years BP was calibrated on the basis of ^{14}C dates on varved lake sediments, as well as paired ^{14}C/uranium-thorium measurements cave speleothem samples as well as on coral and foraminifera obtained from marine cores.

Figure 3 plots the offset from 0 to 50,000 years using the same calibration data set used to produce Fig. 2 (Reimer et al. 2013). The time period covered by Fig. 2 is indicated by the rectangle in lower left quadrant of Fig. 3. The offset values have been calculated for the period from 15,000 to 50,000 years BP based on data obtained from a complex set of temporal proxies already noted combined to form the most recent internationally agreed upon calibration data set. Based on this data, we can see in Fig. 3 that a ^{14}C age determination of 25,000 years BP is considered to be about 4000 years "too young" and almost 5000 years BP "too young" at about 40,000 years BP when compared with assumed "real" or calendar time.

Figures 2 and 3 illustrate both the long-term or major trends in ^{14}C secular variation offsets as well as the shorter-term, rapidly changing "warps" in the ^{14}C time scale. The implications for calibration of ^{14}C values due to the magnitude of some shorter-term variations are illustrated in Fig. Fig. 4a and b. Calibration of the conventional ^{14}C value of 2450±15 years BP is illustrated in Fig. 4a while calibration of 2300±15 years BP is presented in Fig. 4b.

We have already noted that all properly cited ^{14}C age values include a term that states the statistically based precision of a ^{14}C age expression. We also stated that this term is expressed in terms of a statistical concept of sigma (σ). On the vertical axis of both Fig. 4a and b, the ^{14}C ages of two examples are plotted in terms of their $\pm 1\sigma$ (dark shaded area), $\pm 2\sigma$ (dark and lighter shaded areas), and $\pm 3\sigma$ (the entire area under the curve) values on the vertical axis. The dark shaded irregular, ribbon-like, plot of varying width running generally in a diagonal direction through these plots – sometimes referred to as the "calibration curve" – represent the relationship between the ^{14}C ages and the known ages of the series of samples used for the current ^{14}C calibration data set, IntCal13. The varying widths of this plot provide the $\pm 2\sigma$ precision of the calibration data at each particular point along the calibration curve (Stuiver and Reimer 1993).

Because of the variable or "accordion-like" characteristics of the plot of relationship between ^{14}C time and solar time as illustrated in this mid-first Millennium BC period, the calibration of these two values only 150 ^{14}C years apart reveals that the "real-time" equivalents of these two ^{14}C ages produce significantly different results. The calibration data associated with the 2300±15 BP ^{14}C-content inferred age value reflects a period when the contemporary ^{14}C activity in the

Radiocarbon Dating in Archaeology, Fig. 3 Amount of deviation (in years) between ^{14}C ages and calibration sample ages used in IntCal13: 0–50,000 cal BP (Reimer et al. 2013). The area enclosed by lines in the lower left quadrant represents the time period calibrated using tree-ring data as plotted in Fig. 2. The remainder of the plot represents the results of comparisons of ^{14}C values with non-tree-ring dating proxy data incorporated into the international agreed upon calibration data sets. See text for explanation (Source: Taken from Taylor and Bar-Yosef 2014, Fig. 2.10. Original plot provided by PF Reimer and R. Reimer, Queens's University Belfast, personal communication, 2013)

atmosphere was undergoing rapid change. This allows a much more precise resolution of the real time equivalents of a given ^{14}C concentration measured in a sample which had been living during this time period. As plotted on the horizontal axis of Fig. 4a, the $\pm 2\sigma$-based calibrated range for 2300±15 years BP ranges over a 30 year spread from 400 to 370 BC.

In contrast, the calibration data associated with the ^{14}C age of 2450±15 BP falls on a lengthy plateau in the ^{14}C time scale. In this case, the ^{14}C activity in calibration samples range over about a 350 year period. This data indicate that, during that interval, the ^{14}C time scale is "warped" or significantly spread out, i.e., the ^{14}C content of samples, on a decade by decade and century by century basis, had not been changing as rapidly as it had only a 150 years previously. In Fig. 4b, the plotted ^{14}C value intercepts at multiple points at varying levels of statistical significance, the calibration data over almost the entire 350 year time span of this plateau. Thus the calendar age equivalents of this particular ^{14}C value as expressed at various levels of statistical significance range over the 350 year spread from about 750–400 BC.

In this discussion, we have expressed ^{14}C values – both conventional and calibrated – using the phrase "years BP" meaning "years before present." In most sources, standard or conventional ^{14}C values are typically expressed by simply stating the age followed by "BP," i.e., 2000±35 BP meaning "2000±35 years before the present." Calibrated ^{14}C ages are typically cited in terms of "cal BP" meaning "calibrated

Radiocarbon Dating in Archaeology, Fig. 4 (**a**) Plot of calibrated ^{14}C values of 2300±15 BP employing Calib 7.0 calibration protocol (Stuiver and Reimer 1993) and IntCal13 data (Reimer et al. 2013). The dark zones in the areas under the curves representing the ^{14}C BP values and the calibrated span are 1σ ranges while the lighter portions are the 2σ ranges (Source: Taken from Taylor and Bar-Yosef 2014: Fig. 5.9). (**b**) Plot of calibrated ^{14}C values of 2400±15 BP employing Calib 7.0 calibration protocol (Stuiver and Reimer 1993) and IntCal13 data (Reimer et al. 2013). The dark zones in the areas under the curves representing the ^{14}C BP values and the calibrated span are 1σ ranges while the lighter portions are the 2σ ranges (Source: Taken from Taylor and Bar-Yosef 2014: Fig. 5.10)

years before the present" or "cal BC or cal AD" meaning "calibrated years BC" or "calibrated years AD." Some publications employ a terminology which substitutes the expressions "CE" (Common [or Current] Era) for AD and "BCE" (Before [the] Common [Current] Era) for BC. For more information on the typical use of these protocols, please refer to Taylor and Bar-Yosef 2014: 124–129.

Future Directions

The "radiocarbon revolution" (Renfrew 1973) which was initiated more than six decades ago by Willard Libby and his research collaborators actively continues, with ^{14}C often playing a central role as the archaeological chronological court of final appeal. Radiocarbon data have been and will undoubtedly continue to be called upon on many occasions to resolve uncertainties and controversies concerning chronological ordering for cultural materials, including, in some cases, historical period artifacts of problematical authenticity, as well as human skeletal remains of disputed age.

For archaeologists and geologists, the most immediate and obvious impact of the ^{14}C method on the conduct of archaeological research has been the availability of a fixed-rate temporal scale of worldwide applicability for the terminal phases of the Late Quaternary. In providing a common frame of temporal reference for this period, it can be argued convincingly that ^{14}C data made a *world prehistory* possible by contributing a time scale which transcended local, regional, and continental boundaries. As Grahame Clark (1970: 38) noted, ^{14}C dating "has contributed more than any other single factor to complete the world coverage of prehistoric archaeology, not to mention the way it has helped scholars to synchronize phenomena in different parts of the world." Without the time scale provided by ^{14}C data, prehistorians would still be, in the words of J. Desmond Clark, "foundering in a sea of imprecisions sometimes bred of inspired guesswork, but more often of imaginative speculation." (Clark 1979: 7)

For archaeologists, a less immediately recognized contribution of ^{14}C data has been the fact that ^{14}C-based age estimates provide a means of deriving chronological relationships totally independent of assumptions about cultural processes and completely unrelated to any type of manipulation of artifacts. When pressure to derive chronology primarily from the analyses of artifact data was reduced, inferences about the long-term evolution of human behavior based on variations in environmental, ecological, or technological factors could be aggressively pursued employing an independent chronological framework (Bronk Ramsey 2008).

The great success of the ^{14}C method also provided a major impetus for interdisciplinary research in archaeological studies. The ^{14}C dating method provided one of the major catalysts that moved archaeologists increasingly to direct their attention to analytical and statistical approaches in the manipulation and evaluation of data as well as to maintain long-term collaborative relationships with colleagues in other scientific disciplines. Those long-term collaborative relationships will continue to be expanded into more and more areas of research (Clark 1970)

It was therefore entirely understandable that Frederick Johnson, an American anthropologist and archaeologists, an early proponent of interdisciplinary studies in archaeology, became an early advocate of the critical utilization of ^{14}C method among his colleagues. The general theme of his concerns at the inception of the method is still relevant as we look forward to the continuing expanding horizons of the application of ^{14}C in archaeological studies: "[P]rogress in the development of . . . [radiocarbon dating] depends to a large degree upon the character of the collaboration [between archaeologists and other scientists]. The laboratory procedure involves theories in physics and chemistry which for the most part are outside the experience of almost everyone who has a sample to be dated. On the other hand, the results secured are of little consequence

unless they are directly or indirectly related to some stratigraphic sequence. The value of the laboratory results is enhanced by critical evaluation by other scientists. Most particularly, the reverse is true. This involves continual examination of all basic theory and hypotheses by everyone concerned. The future value and usefulness of the method depends in large measure upon the success of continued collaboration between physicists, archaeologists, geologists, botanists, and others" (Johnson et al. 1951: 62).

This injunction assumed an even greater significance with the introduction of accelerator mass spectrometry (AMS) technology for ^{14}C measurements. AMS methods permit analyses to be conducted on microgram amounts of organics and opens up the possibility of extending the ^{14}C dating range. For archaeologists and Quaternary geologists, the utilization of submilligram-size samples will require an even more rigorous attention to the evaluation of geological, geochemical, and archaeological contexts of samples. The need for interdisciplinary cooperation and collaboration will become even more critical as AMS technology assumes an ever increasing role in the ^{14}C measurements of archaeological and other terminal Late Quaternary paleoenvironmental and paleoecological materials (Pollard 2009).

Rapa Nui

Jo Anne Van Tilburg
Cotsen Institute of Archaeology at UCLA, Los Angeles, CA, USA

Introduction

The megalithic culture of Rapa Nui was created by Eastern Polynesians on a single island located in the remote eastern Pacific Ocean and in the Southern Hemisphere at 27° 9'S latitude and 109° 26'W longitude (Fig. 1). The defining megalithic components are sculpture (stone statues; *moai*) and architecture (religious centers; *ahu moai*). A Neolithic (stone-based) society, ancient Rapa Nui was a chiefdom in which the highest-ranking male (*'ariki mau*) was believed to be descended from deified ancestors who were major gods.

Rapa Nui marks the east vertex of what archaeologists, anthropologists, linguists, and art historians agree is a discrete Pacific island cultural area called the Polynesian Triangle. New Zealand (Aotearoa) surmounts the west vertex of the Triangle and consists of two large islands comprising over 500,000 km^2, and the archipelago of the Hawaiian Islands marks the Triangle's apex. Geographically situated at a straight-line distance of 1924 km east of Pitcairn Island and 3676 km west of today's busy port city of Valparaíso, Chile, Rapa Nui was annexed by that South American nation on September 9, 1888.

Although its surface area is only 163.6 km^2, Rapa Nui is not the smallest of Pacific "high" volcanic islands, which vary from only 0.8 km^2 (Anuta) to 10,458 km^2 (Hawai'i Island) (Kirch 2000:48). In fact, Rapa Nui is more than double the size of all possible islands from which its original Polynesian settlers may have departed, although it does have a highly marginal natural environment. Rapa Nui's nearest neighbors – Henderson Island, an uplifted coral island, and Pitcairn Island, a small, steep volcanic island – were each exploited for desired resources by Eastern Polynesians but never permanently inhabited, and both were eventually abandoned (Weisler 1998).

Rapa Nui: Polynesian Origins

Polynesian migration and island settlement were vast undertakings accomplished in a relatively

Rapa Nui, Fig. 1 Ahu Tongariki, the largest megalithic site in Polynesia

conservative and patterned way. First, a small contingent of seasoned explorers scouted new islands. They did so by sailing against the prevailing winds within increments that grew increasingly more distant from their starting point. These trained and experienced Polynesian voyagers and navigators enacted zigzag searches while seeking signs of land. Once new land was discovered, the search party returned to its home island with the wind and reported their discovery to chiefly leadership. A fully equipped settlement party was assembled of at least 50 or more persons, including women and children or young adults. Traditional Polynesian food plants and some animals were carried aboard the vessel, which was guided by a navigator entrusted with sailing directions. It is thought that most Polynesian groups could maintain sailing directions relatively accurately as oral histories for about four generations (or about 100 years).

The Polynesian story is told through archaeological and linguistic evidence and confirmed by human, plant, and animal DNA analyses. According to the currently accepted chronology, the story began in a region known as Near Oceania during the Neolithic culture history of Taiwan by ~5000 to 4000 BP (2000–1300 BC). The earliest dated, iconic ceramic phase is 2200 BC. It then progressed to the Philippines and spread to Borneo, Sulawesi, and Eastern Indonesia. Austronesian-speaking agriculturalists eventually established an Oceanic homeland in the Admiralty and Mussau islands of the Bismarck Archipelago, perhaps as early as 1500 BC. The archaeological construct known today as the Lapita cultural complex (Lapita peoples) emerged as a blended entity perhaps between ~1410 and 1290 BC.

Eastern Pacific voyages of exploration and those of settlement were originally initiated from the Western Polynesia formative homeland of Tonga–Sāmoa (Finney 1994: 103, Fig. 22). A northern Polynesian voyaging route led eastward out of Sāmoa, and a roughly parallel southern route extended from the Tonga Islands. Analyses of wind patterns indicate that "sailing back and forth across tropical Polynesia was nowhere near as difficult as assumed in isolationist models" and that "two–way voyaging was crucial to the discovery and settlement of the islands" (Finney 1994:265).

The northern route out of Tonga–Sāmoa eventually reached the Marquesas Islands, while the southern route encountered the Cook Islands and extended to the Austral Islands. Finney (1994:264) reports ethnographic research suggesting that the Marquesas may have been settled "by separate migrations, one from Tonga and the other from Sāmoa." Tahiti and the Society Islands, along with the low, widely scattered Tuamotu islands and atolls lie at the heart of Central Eastern (tropical) Polynesia and formed a complex interaction hub. As Finney (1994:266) also notes, that region is a "conglomeration of contiguous and near-contiguous archipelagos" assuring that any Western Polynesian explorers sailing eastward "would have intercepted islands." The greatest challenge was long-distance open-water dispersal to the distant "points" of the Polynesian Triangle. Ethnohistory reports that New Zealand was reached by more than one voyage, and archaeology suggests that perhaps the Hawaiian Islands were as well. Simulation studies and proxy evidence support the thesis that discovery of remote, uninhabited Rapa Nui was from Mangareva (Gambier Islands) via Pitcairn Island or, less likely, from the Austral Islands via the island of Rapa. In either case, discovery may have been a fortuitous accident driven by anomalous oceanic weather conditions caused by El Niño or another such natural event.

Rapa Nui: Human Impact

Satellite imagery clarifies the tectonic situation, topography, and depths of the southeast Pacific Ocean floor underlying Rapa Nui, which is part of the "Easter-Salas y Gómez Seamount Chain," sometimes called the "Easter Island Fracture Zone." The seamounts are ~3000 m above the seafloor, and the chain, which is ~200 m wide, extends over 2900 km from Rapa Nui to the point where it joins the Nazca Ridge at ~27°S. A defining characteristic of Rapa Nui is geographical isolation.

Rapa Nui, Fig. 2 Overview showing part of La Perouse Bay (Hanga o'Honu) and three parasitic cones on Poike slope

Rapa Nui, Fig. 3 Interior of Rano Kau caldera

Rapa Nui is a volcanic "high" island that is geologically quite young (~750 kya). Terevaka is one of its three formative volcanoes and defines the island's maximum elevation above sea level (asl) at 525 m. This elevation may be compared with Mangareva (441 m asl) or Rapa in the Austral Islands (650 m asl). Terevaka means *patron de bote de pesca* or the owner or captain of a canoe (*vaka*). The other formative volcanoes are Pōike (Pú a ka Tiki; 352 m; Fig. 2) and Rano Kau (324 m; Fig. 3). Geological age has implications for soil quality and

Rapa Nui, Fig. 4 Inner region of Rano Raraku and its lake (rano)

erosion, stone conservation, and agricultural productivity.

Rano Raraku (Fig. 4) is the quarry within which precisely 91.3% of 1693 stone sculptural objects (including statues, heads, torsos, and fragments) recorded to date were carved. It is a semicircular erosional geomorphic feature with an elevated rim measuring ca. 800–1000 m across and rising ca.100 m asl in the west and north and ca.160 m asl in the south and east. Rano Raraku contains a rain-fed lake averaging 3 m deep with minor fluctuations, and almost 400 *moai* still remain within the confines of the Rano Raraku statue quarry.

The weathered source rock out of which the *moai* were carved is a cross-bedded lapilli halotuff (Fig. 5). Recent excavations by the Easter Island Statue Project (EISP; www.eisp.org) of two upright *moai* in Rano Raraku inner region demonstrated that the soils nearly burying the statues were deposited post-quarrying and as a direct result of movement caused by rainfall and human activity on the deforested and quarried stone surface (Sherwood et al. 2019; Fig. 6). Following deforestation and quarrying, the surface of

Rapa Nui, Fig. 5 Unfinished megalithic statue (moai) in Rano Raraku quarry

Rapa Nui, Fig. 6 Overview of excavations of Moai 156 and 157, Rano Raraku Inner Region

the lapilli material on the upper slopes weathered, broke down, and then moved downslope to cover many of the statues. The soils thus created are highly productive and create an agricultural area with rich potential. The statues were erected in the fifteenth century and prior to new soil formation and deposition.

The island's climate is subtropical to temperate, but ancient Central Polynesian voyagers probably would have found it cold. At present, the warmest months are January, February, and into March (23.4 °C; 74^0 F). The coolest, wettest months are July and August (17.5 °C). The average annual temperature is 22° C; and average rainfall is between 1250 and 1500 mm per year. Annual rainfall adequate for dry land agriculture is between 1700 mm and 620 mm per year or a mean of ~1100 mm.

The recent average annual Rapa Nui precipitation rate shows an increase of 566 mm and varies from 50 m asl in the coastal plains to more than ten times that (511 m asl) on Terevaka. Outside of Rano Raraku quarry, the porous volcanic soils of Rapa Nui, like those of much smaller Pitcairn Island or Rapa, do not hold rainwater efficiently. Runoff depletes soils, and water travels in thousands of naturally eroded channels to coastal outlet locations to emerge at low tide. These outlets are "dry in the summer months," and their "low seasonal stream flow would not have supported an irrigation system" (Stevenson and Haoa Cardinali 1998:7). Minor sources of brackish water exist all along the coastline, and some researchers have suggested that they were key determiners in siting major *ahu moai*. However, this is highly unlikely as many water channels or collection areas are nowhere near *ahu moai*.

An important point is that rainfall predictability is as important as the actual amount of precipitation, noting that the more variable the rainfall, the greater the risk of crop failure or reduced yields. The issue of predictability is addressed in Polynesian chiefdoms both practically and spiritually, with observed changes in rainfall levels or wind directions remembered and preserved in oral traditions by mariners and agriculturalists, while control over such events was sought through priestly ministrations.

Métraux (1940:11) noted that on the north coast, some ravines (*ava*) are "clearly not due to erosion" and were probably constructed to manage water. Major *ahu moai* sites such as the Tahai ceremonial center, Tepe'u, Vai Tara Kai Ua, Puna Mareŋo, Ovahe, and many others from Vinapū to Akahaŋa all have well-known minor springs or outflow water sources, and at Akahaŋa, Ura Uraŋa Te Mahina, and Vaihū, the seasonally available rainwater runoff could be substantial.

The most important recent finding is a probable water management system documented by Vogt and Kühlem (2017). Their extensive excavations provide archaeological evidence of stone-faced earthen installations in a seasonal watercourse known as *ko te ava a raŋa uka a toroke ha'u* that

terminates at the coastline six kilometers away at Opipiri near Ahu Akahaŋa. Their new data unite and explore the site's extensive pavements and water storage features. The excavators suggest that a grove of palms existed in this upland area quite late in time and their preliminary radiocarbon determination for the site is cal AD 1477–1647. This date range is contemporaneous with the most recent dates from Rano Raraku (Sherwood et al. 2019).

Island-wide drought ($P_m = 591$ mm) may have occurred at Rapa Nui AD 1570–1720 due, in part, to natural events known as La Niña and El Niño, which alter sea surface temperatures in the tropical Pacific. Finney (1994) suggested that Rapa Nui "cultural collapse" could be related to drought. However, he also noted that major drought, if it occurred, could also just be a trigger for other environmental problems. A drought lasting 5 years or more would have been devastating if not terminal to the Rapa Nui agricultural economy (Van Tilburg 1994).

The remnants of 17 sea ramps occur along the coast, and most of them have extensive pavements located behind *ahu moai* sites. Some ramps have post-construction features (including at least one burial) that are evidence of adaptive reuse. An elaborate sea ramp at the reconstructed Tahai ceremonial center was characterized during restoration as a "canoe ramp" (Fig. 7). This may be correct, but it is impossible today to bring a large canoe through the current rocky shoreline and up that ramp.

The deep, traditionally relatively cold (18 °C at 200 m) waters of Rapa Nui spatially restrict the relative growth rates of corals. Of six species of corals (*puŋa*; *punga*), two are endemic to Rapa Nui. Carved coral eyes were once inserted in prepared sockets of statues upright on *ahu moai*. To date, the coral eyes are known to have survived relatively intact from excavations at only two major *ahu moai* locales: Vinapū and Ahu Naunau III, 'Anakena.

Six named fishing zones extend out to sea from the shoreline and correlate with the types of fish found within them. The greatest diversity of species is found in nearshore waters. Randall and Cea (2011:2) report a total of 169 species of Rapa Nui fishes, of which 139 are shore fishes living in waters less than 200 m deep and 21.7% of the

Rapa Nui, Fig. 7 Tahai Ceremonial Center with view of paved sea ramp in foreground

total is endemic. Polynesian fishhooks are a well-studied category of artifacts throughout the Pacific, and Rapa Nui marine technology includes one-piece and two-piece hooks. Large one-piece stone hooks (*mangai*) were used in deep water to catch prestige fish, including especially tuna, and may have been worn as amulets. The stone hook is a local innovation with a known counterpart from Pitcairn Island. It is also similar to one-piece bone fishhooks from Mangareva.

The number of bird species lost to extinction after humans colonized the Pacific islands is staggering. The most comprehensive Rapa Nui avifauna data are from ʻAnakena, where 14 species of seabirds and 6 undescribed taxa are reported (Steadman et al. 1994). Artifacts included a needle made from the bone of a Murphy's petrel (*Pterodroma ultima*), today a threatened species worldwide.

Rapa Nui has the dubious distinction of possessing one of the least diverse assemblages of food plants of any high island in Polynesia. About 42 species of vascular plants are reported. Of these, ~30 to 32 species are native and 4 or 5 are indigenous. Among the latter are leafy plants such as *Chenopodium glaucum?*, *Ipomoea pes-caprae*, *Tetragonia expansa*, and *Solanum forsteri.* Indigenous famine foods include especially ferns such as *Vittaria elongata* (*kavakava atua*) and possibly even sedges (grasses). Fortunately, several important taxa survived overseas transport by voyaging Polynesians and subsequently thrived on Rapa Nui, including *Colocasia esculenta* (dryland taro; *taro*); *Dioscorea* sp. (yam; *uhi*); *Cordyline fruticosa* (ti); *Saccharum officinarum* (sugarcane; *toa*); *Musa sapientum* (banana; *maika*); and *Curcuma longa* (turmeric; *pua*).

At the time of human arrival Rapa Nui was forested with an unknown species of palm now designated as *Paschalococos disperta* Dransfield. There are about 100 genera and 15,000 species of palms in the world. Pacific palms attain heights of 15 m or more. *Paschalococos*, however, is thought to have reached ~20–25 m tall and perhaps as much as 2 m in diameter. Because of its width and irregular shape it is hard to imagine they were useful in moving and raising *moai*, but the small coconut fruits were edible and the fronds, which may reach 5 m long, were used as thatch in Rapa Nui house construction. Instead, there were big trees of hardwood like *Alphitonia zizyphoides* (*toi*) and *Elaeocarpus rarotongensis*, which attains 15–20 m tall and were probably important for construction and canoe building.

A palm deforestation event at Ma'uŋa Orito AD 1100–1200 was followed by extensive gardening. Deforestation in discrete portions of Pōike began ca. AD 1280 and extended to ca. AD 1500–1675 (Mieth and Bork 2010:422–423). Forest clearance and the resultant heavy erosion negatively impacted agriculture and buried the structures on the lower portions of the Pōike slope. Land use in the downslope areas of eastern Pōike was abandoned post-ca. AD 1490, and a second land use period occurred southwest of Pōike ca. AD 1500–1675.

At Western contact Rapa Nui was completely deforested not only of palm but of all other trees. This was a direct result of human intervention. That is, progressive deforestation through cutting and burning vegetation created open land for planting, a common practice in many areas of the world and known as "swidden agriculture." Among economically important trees and shrubs, two had the highest value: *Triumfetta semitriloba* (Tiliaceae; *hauhau*) and *Broussonetia papyrifera* (paper mulberry; *mahute*). As everywhere in Polynesia, these trees were basic to creating the pre-contact lifestyle. Paper mulberry was used to make a whitish-gray fabric used for capes and other clothing. *Hauhau* provided cordage, twine, ropes, rigging, sails, and in some cases also bark cloth. *Sophora toromiro* (*toromiro*) was an important hardwood used in construction and the carvers' art. Sandalwood (*Santalum*; *naunau*) was used in woodcarving; it apparently had sacred connotations or associations. Other useful trees included *Caesalpinia major* (Caesalpiniaceae; *ngaoho*) and *Thespesia populnea* (Malvaceae; rosewood; *mako'i*).

Historical Background

Linguists conservatively suggest that Rapa Nui may have been discovered by Polynesians as

early as A.D. 800 but probably by at least the mid-AD 900 s. By the mid-AD 1200s, the well-established human population was dispersed widely on the landscape. To date, 27,000 georeferenced sites, features, and objects have been recorded by multiple survey teams. The numbers of habitations within that number suggest that population levels certainly reached 10,000 persons and perhaps attained nearly double that number. Thatched houses of stone and wood proliferated among agricultural fields, outdoor cooking areas, and kitchen gardens and jointly owned lineage territories were marked by large-scale ceremonial centers (*ahu*). Small, portable, roughly carved stone anthropomorphic figures were made and used by individuals and families. Gradually, these became standardized, iconic stone figures in male human form (*moai*) that represented major gods. Over time, multiple lineage groups consolidated into two major sociopolitical confederations linked to legendary personages and ranked according to primogeniture. The Western, higher-ranked group was known as Tu'u; the Eastern, lower-ranked group was Hotu 'Iti.

The proliferation, morphological similarity, and distribution of *moai* on the island and within Rano Raraku are independent but related characteristics indicative of production task management and supervision, time investment, and craft specialization. The exclusivity of Rano Raraku tuff use in *moai* production establishes ritualization of the stone and, by extension, allows conceptualization of the quarry itself as sacred. The numbers and sizes of *moai*, including those remaining in the quarries, point unequivocally to statue carvers as a non-subsistence-producing elite group. Such groups in other societies achieve prestige and privilege but also can become an economic burden on society. Other individuals with lesser expertise (e.g., apprentice carvers) likely performed lower-level support tasks, possibly including basaltic stone tool production. The *moai* artisans (*taŋata maori aŋa moai ma'ea*) were members of an elite occupational group and cooperated with the paramount chief (*ʻariki mau*), those in his direct line of descent (*ariki paka*), and the highest-ranking priests (*ivi atua*) who officiated at the *ahu.* Ethnographic and ethnohistoric sources report that sub-leadership ranks were composed of chiefly advisors (*hōnui*).

Key Issues and Current Debates

Certain issues have dominated Rapa Nui scholarship for several generations, including the chronology of discovery and settlement, the trajectory of megalithic development, and population numbers and demographics. In general, a major scholarly interest is the interactive functional relationships of a hierarchical social system (chiefdom) supported by an agrarian economy within a marginal natural environment.

Debates about Rapa Nui origins were once tied to the question of how and when the sweet potato (*Ipomoea batatas*) was introduced to Eastern Polynesia. A staple food on Rapa Nui at Western contact, sweet potato evolved in South America – its parent plant is the wild *Ipomoea trifida* – and Quechuan speakers of the Andes name it *cumal*, *cumar*, or *cumara*. In the Rapa Nui language, it is *kumara*, a word that appeared by or before AD 800 based upon the lexical reconstruction of ∗*kūmara* to the Proto-Polynesian (PPN) level (Kirch and Green 2001). For most researchers, the question of sweet potato introduction is settled: "It is entirely plausible that at least one [Polynesian] voyaging canoe reached South America to establish contact and return with sweet potato tubers" (Kirch 2017:208–210).

The earliest directly dated sweet potato in Eastern Polynesia is a tuber fragment found in the Kohala Field System of Hawai'i Island. It produced a radiocarbon date of cal AD 1290–1430. Starch grains were found on a shell tool within a context possibly dating as early as the thirteenth century or to the late fourteenth century in the Anaho Valley, Nuku Hiva, Marquesas Islands. Fragments of carbonized sweet potato on Mangaia, Southern Cook Islands, provide a conventional radiocarbon date range of cal AD 1448–1616, thus supporting sweet potato transfer into central Polynesia no later than the end of the fourteenth century AD. EISP excavations in Rano Raraku, the megalithic *moai* quarry, returned a directly comparable radiocarbon determination

of cal AD 1492–1646 (95.4% probability) on a carbonized sweet potato fragment (Sherwood et al. 2019).

Compilations of over 468 radiocarbon dates and area-wide site and demographic analyses suggest permanent and widespread Polynesian settlement and agricultural practices on Rapa Nui by at least AD 1200, with megalithic construction of major *ahu* ceremonial sites adorned with upright *moai* beginning ca. AD 1100–1200. Excavations in Rano Raraku Inner Region establish that standardized "classic" *moai* 6–7 m tall were being actively carved by cal AD 1455–1605 and then raised and retained permanently in place before cal AD 1510–1645 (95% probability). Carving of megalithic *moai*, many of which were 10 m or more tall, ended permanently by Western contact in 1722.

International Perspectives

International perspectives capable of producing research insights into the Rapa Nui past include genetic tracing, and such studies have implications for the modern community through concerns centered on the repatriation of human remains. A substantial problem for osteological data analyses is that cremation, which took place at the large ceremonial mortuary sites, obliterated most of the earliest skeletal evidence. Later burial practices during which ceremonial structures were demolished and rebuilt as semi-pyramidal *ahu*, along with indiscriminate collecting until at least 1872, caused extensive admixing of human remains. However, there is consensus that Rapa Nui crania are related to other Eastern and Central Polynesian cranial series and that some close biological connections exist between crania from Easter Island and the Gambier Islands (Mangareva).

It is increasingly evident that rapid forest replacement by grasses and sedges took place on Rapa Nui during the late Holocene. There is scientific consensus that deforestation – wherever it is recorded in closed Pacific island ecosystems – is attributable to human clearance. Sustainability of island life in the past and throughout the Pacific today is being assessed in the context of climate change.

Lake core evidence is important in establishing a clearer understanding of hypothesized "climatic forcing" of past and present cultural changes. For pre-Western contact Polynesia, few would question the assertion that anthropogenic environmental transformations were intense and extensive, although the full potential effects of climatic anomalies on such events remain to be analyzed within the context of international concerns about human behavior and the environment. Deforestation was fundamental to establishing successful agriculture on Polynesian islands, and knowing more about such patterns offers insight into the proportionate impact of human and natural events on the global cultural trajectory (Van Tilburg 1994:162). There is a need to continue widespread data collection and develop new analysis strategies in order to obtain insight into climate-driven cultural changes.

Future Directions

Three fields of inquiry suggest new opportunities for Rapa Nui research: linguistics, iconography, and soil micromorphology. Polynesian outliers are islands and atolls lying outside of the geographical boundaries of the "Triangle" yet displaying well-documented Polynesian archaeological and linguistic affinities suggesting voyaging contacts between, for example, Micronesia and Polynesia. Wilson (2012) traces a linguistic chain of Eastern Polynesian settlement to the Northern Outliers based upon 51 lexical and 22 grammatical reconstructions shared within a Central Northern Outlier-Eastern Polynesian subgroup. The Northern Outliers are the atolls of Kapingamarangi and Nukuoro. Wilson's research modifies the "standard subgrouping" linguistic model (see above) but continues to assert that Rapa Nui branches out of Proto-Eastern Polynesian and is a conservative language with important retentions.

A recent and rapid model of initial Eastern Polynesian settlement (AD 1025–1120) by some researchers. However, they presume that the Society Islands are the central "homeland" locale from which other areas of Eastern Polynesia were

settled. In contrast, Wilson (2012) argues that "linguistic similarity, often used to trace phylogenetic relationships of populations in East Polynesia" supports a model of "relatively slow, incremental expansion" that demands reconsideration "especially in the case of Rapa Nui." The Marquesic–Tahitic linguistic divide presents

> a challenge for [the Wilmshurst et al. 2011] scenario and its claim of the Society Islands as the homeland from which all other [Eastern Polynesian] areas were rapidly settled. The language native to the Society Islands, Tahitian, reflects Tahitic innovations that are not only absent from Rapanui but also absent from Marquesan, Mangarevan, and sometimes Hawaiian. These Tahitic innovations are spread, however, throughout the languages of the Cooks, Australs, Tuamotus, and New Zealand, [thus] supporting a distinctive unified history for these languages. (Wilson 2012:352–353)

Wilson's (2012) research takes a fresh look at integrating Polynesian Outliers into the linguistic history of Eastern Polynesia. It encourages broader contextual consideration of Rapa Nui linguistic and aesthetic roots, some of which are embedded in the Gambier Islands but also the Cook Islands. This has implications for the discussion of Rapa Nui origins, not as direct voyaging contacts but, rather, as subtle influences only detectable through careful comparative analyses of fields such as iconography.

Secondly, it has been recently shown that the application of petroglyphs to the standing statues in Rano Raraku was a secondary activity associated with late developing iconographic and ideological trends that followed the rejection of the *moai* as symbol and the collapse and redirection of the principles that dictated its cultural value (Sherwood et al. 2019). There is a continuity and affinity in all Rapa Nui arts, but there are also distinct stylistic trends that signal philosophical growth and change. Further work is needed, but there is very reason to believe that greater understanding of the megalithic culture lies in discerning the encoded meanings in patterned iconographic expressions of multiple motifs within iconographic types (e.g., tattoo, rock art, and portable and megalithic objects).

Finally, traditional Polynesian cultivars with potentially high productivity levels, including banana, sweet potato, and paper mulberry were present in Rano Raraku inner region, and statue quarrying there significantly enriched the soils (Sherwood et al. 2019). Excavation demonstrates that Rano Raraku soil/sediment itself was a valuable resource and, perhaps as the authors above suggest, an exchanged commodity. Soils micromorphology offers empirical and abundant botanical evidence of cultivars buried in the south slope of Rano Raraku inner region, thus revealing a mixed-crop production system located for an extended time among the quarries and standing *moai.* There is still much to learn about the Rapa Nui ecosystem use and misuse, including land management and ceremonial activities. However, the richly endowed agricultural area of Rano Raraku, and specifically the soils contained within it, offers new and more nuanced insights into the interactive nature of the prehistoric Rapa Nui *moai* production system and its related economy, thus offering new directions of research emphasis. Perhaps, at long last, we have the potential to lay to rest permanently some of the longstanding "mysteries" of Rapa Nui. In response, new scientific challenges will surely emerge.

Raposo, Luìs

Luìs Raposo
Museu Nacional de Arqueologia, Lisbon, Portugal

Basic Biographical Information

Luìs Raposo (Fig. 1) was born in Lisbon, Portugal, in 1955. He was Director of the National Archaeology Museum, Portugal, between 1996 and 2012, where he became Head of the Research Department since 2013. In 2000, Luìs Raposo was appointed as a member of the Board for the Gulbenkian Archaeology Award. In 2005 he became an invited professor at the University of Lisbon. In 2009 he became Chair of the Board of the Portuguese National Committee of ICOM and a member of the Advisory Committee of the Portuguese National Committee of UNESCO. He became Chair of the Fiscal Committee of the Portuguese Association of Archaeology in 2012, being earlier Chair of the Directive Board (1998–2000), the Chair of the General Assembly (2000–2010), and Chair of the Fiscal Committee of the Professional Association of Archaeologists.

Major Accomplishments

Luìs Raposo is an expert in ancient prehistory (Paleolithic). His main geographic areas of activity are the Lower and Middle Paleolithic of the Tagus Valley and Lisbon region (Raposo 1996) and the Epipaleolithic of the Alentejo Littoral (Raposo et al. 1993, 1994). His main subjects of research are a critical review of the earliest human occupations in Portugal and Iberia; evolution of Acheulean in the Tagus Valley (Raposo 1996); definition of the late survival of Neanderthals in Portugal and Southern Iberia (Raposo et al. 1999, 2000, 2007); macrolithic postglacial industries in river valleys and littoral fossil beaches (Raposo et al. 1982, 1984); and technology and typology of lithic assemblages (Raposo et al. 1975; Raposo and Santonja 1995).

Luìs Raposo has been a collaborator in the installation of local and regional archaeology museums in Portugal and coauthor, scientific consultant, or executive commissioner of national and international exhibitions (Museus de Arqueologia-Tomar 2009). In his role as an invited professor and recognized expert, he has supervised several postgraduate research projects, including students who hold scholarships from the Calouste Gulbenkian Foundation, and participated in several academic juries, in different countries.

Luìs Raposo has been instrumental in protecting and promoting Portugal's archaeology and cultural heritage at a governmental level and internationally. He has been the representative of Portugal and/or of the Ministry for Culture on

Raposo, Luìs, Fig. 1 Luís Raposo at the National Museum of Portugal

various committees, responsible for research projects approved and/or financed by the Ministry of Culture and the Ministry of Science, also having helped to develop several agreements on bilateral international cooperation. He is a member of the Network Coordinating Committee for the project "The Palaeolithic Occupation of Europe," which was created by decision of the European Science Foundation's governing bodies, in December 1992. He is a member of the editorial boards of several journals in Portugal and abroad, namely, "Al-Madan" "Trabajos de Prehistoria," and "Museologia.pt" (Museology.pt), and a participant in numerous national and international scientific meetings.

Luìs Raposo is a coauthor of university textbooks and synthesis works in the fields of museology (Raposo et al. 2009), archaeology, and history (Raposo et al. 1975, 1982, 1984, 1993, 1994, 1996, 1999, 2000, 2007; Raposo and Santonja 1995). He has published around 230 titles between 1972 and 2012 as part of a vast specialized bibliography on prehistory, archaeology, and museology, published in national and foreign monographs and specialist journals.

Rapp, George R.

Andrea K. L. Freeman
Department of Archaeology, University of Calgary, Calgary, AB, Canada

Basic Biographical Information

Affectionately known as "Rip," George Robert Rapp, Jr. (1931–) began his career as an experimental geochemist, earning his B.A. in geology and mineralogy in 1952 from the University of Minnesota and a Ph.D. in geochemistry from Pennsylvania State University in 1960. His early research focused on the synthesis of minerals such as zoisite and idocrase (doctoral work) and mineralogical studies of materials from South Dakota while serving on the faculty at South Dakota School of Mines and Technology. In 1965, after a year on sabbatical at the University of Minnesota Twin Cities, Rapp joined the faculty there as an Associate Professor of Mineralogy. He remained at the University of Minnesota, on both the Twin Cities and Duluth campuses for the duration of his academic career. Rapp served as Dean of the College of Letters and Science, then of Science and Engineering, as well as Director of the Archaeometry Lab (UMN-Duluth) for many years before retiring as a Regent's Professor of Geoarchaeology in 2003. He retired to Tucson, Arizona, and continued his publishing there.

Major Accomplishments

Rapp's principal contribution to archaeology is his work in developing the field of geoarchaeology or "archaeological geology" (Rapp and Gifford 1982). He founded the Archaeological Geology Division of the Geological Society of America. At the University of Minnesota, Rapp cofounded the Center for Ancient Studies (early 1970s), which later became the Interdisciplinary Archaeological Studies program. This was perhaps the first interdisciplinary graduate program in geoarchaeology and archaeological science. During this time, he produced a number of influential papers defining the field of geoarchaeology and the role of archaeological geologists as practitioners (Rapp Jr. 1970, 1975; Rapp and Gifford 1985). Both the graduate and undergraduate programs that he directed produced numerous students who went on to distinguished careers in the field (Julie Stein, Zhichun Jing, John Gifford, and Christopher Hill). Additional evidence of his lasting influence on geoarchaeology include *The Directory of Graduate Programs in Archaeological Geology and Geoarchaeology* (now maintained by members of the Archaeological Geology Division of GSA) and the Division award (the Rip Rapp Award) so named for its first recipient.

Rapp's first assignment as an archaeological geologist was as associate director of the Minnesota Messenia Expedition and its excavation of

the Bronze Age site of Nichoria in southwestern Greece (McDonald and Rapp 1972; Rapp and Aschenbrenner 1978). His work on this project combined a childhood interest in classical archaeology with his research strengths as a geoscientist (Jing 2007). Rapp's research in the circum-Mediterranean later included sites and regions in Cyprus (Swiny et al. 2003), Turkey, Israel (Herzog et al. 1989), Egypt (Rothe et al. 2008), and Tunisia (Gifford et al. 1992). These resulted in some of the first geoarchaeological explorations of coastal landscapes and paleogeography. Most notable among these were his investigations of the coastal regions surrounding Troy (Kraft et al. 2003), the Peloponnese (Kraft et al. 1977), Ephesus, Pylos, and Thermopylae (Kraft et al. 1987).

As with much of Rapp's career, his studies of artifact copper stood at the forefront of new advances in the discipline of sourcing using trace elements (Rapp et al. 2000). His research on archaeological copper followed nearly every part of the globe where Rapp left his mark, including his long tenure in the Great Lakes region, his retirement in Arizona, and his geoarchaeological research in China. His latest efforts in developing the new field of archaeomineralogy (Rapp 2009) follow naturally from this work and his initial research interests.

Rapp's research in China began in the 1990s, working with K.C. Chang on the Shangqiu project (Jing et al. 1997) and continued with Z. Jing through his retirement as part of the Anyang and Huanbei projects. Employing both traditional coring and more modern geophysical survey and satellite remote sensing, Jing and Rapp discovered important Bronze Age cities under meters of silt (Jing et al. 1997; Jing 2007). His work in China and the Mediterranean illustrate Rapp's strengths in forging and maintaining successful interdisciplinary and international collaborations.

While the research outlined above is central to defining the principal foci of Rapp's career, it would be unfair to characterize his contributions to archaeology as limited to these themes. Rapp is perhaps the consummate driver of new ideas. His graduate students, and undergraduates who trained with him initially, have been involved in many related but diverse facets of geoarchaeology including archaeological sediments and phytolith research (Rapp and Mulholland 1992). His extensive publication record includes the development of textbooks in geoarchaeology (Rapp and Hill 2006) and mineral encyclopedias (Roberts et al. 1974).

Rathje, William Laurens

Michael Brian Schiffer and J. Jefferson Reid
School of Anthropology, University of Arizona, Tucson, AZ, USA

Basic Biographical Information

William Laurens Rathje (1945–2012) was born in South Bend, Indiana. After receiving his B.-A. degree in anthropology from the University of Arizona in 1967, he attended Harvard University on a National Science Foundation Graduate Fellowship, where in 1971 he was awarded the Ph.D., also in anthropology. His museum-based dissertation, *Lowland Classic Maya Socio-Political Organization: Degree and Form Through Time and Space*, was directed by Gordon R. Willey. Even before the dissertation had been completed, Rathje in 1970 returned to the University of Arizona as a faculty member, where he remained until retirement in 2000. After retirement, he spent several years at Stanford University teaching with Michael Shanks.

Major Accomplishments

Rathje's contributions to anthropological archaeology were significant in a wide range of research areas. His numerous papers on Mesoamerican archaeology published in 1970–1978 established Rathje as one of the preeminent Mayanists of his generation. These publications, which continue to garner citations, set the agenda for studies of social organization, the role of religion in economic systems, mortuary assemblages, and exchange systems.

Rathje is best known for his study of modern middens. In 1973 he established an entirely new field of applied archaeology that came to be called garbology. The Garbage Project, the first long-term study of modern material culture, analyzed refuse – sometimes very fresh, sometimes from landfill excavations – in Tucson and other cities in the United States as well as from Canada, Japan, and Mexico. Although many prehistorians disdained the Garbage Project, Rathje was successful in obtaining funding from corporations and governments for more than two decades because household garbage could furnish information available through no other means on topics such as the social parameters of diet, household discard patterns and the composition of refuse, food waste, hazardous materials, and effectiveness of recycling campaigns. Not only did these studies furnish substantive results, but they also contributed new unobtrusive methods for measuring human behavior. The project brought to light differences in front door (interviews) and back door (garbage) evidence on consumption patterns. For example, they found that consumption of tobacco and alcohol was significantly underestimated in interviews.

Although Garbage Project findings were often published in journals not read by archaeologists – ranging from *Waste Age* to *Journal of Nutrition Education* – Rathje and his collaborators took

pains to bring major findings and methods to the attention of our discipline in many edited volumes and journal papers. He also wrote with Cullen Murphy, *Rubbish! The Archaeology of Garbage* (1992), a popular book that helped to spread the garbage gospel far and wide. For three decades the Garbage Project received more media publicity than any other University of Arizona research project. To millions of Americans, he was the public face of archaeology, highly visible on television and radio, in newspapers and magazines, and as a keynote speaker at trade group conventions. He even testified in Washington before a Congressional committee.

In recognition of the immense public impact of the Garbage Project, Rathje in 1990 received the highly prestigious AAAS/Westinghouse Award for Public Understanding of Science and Technology. And on the basis of his contributions to applied anthropology, in 1992 he was the recipient of the American Anthropological Association's Solon T. Kimball Award.

Rathje's scientific interest in modern material culture and human behavior has had a broad theoretical impact in archaeology. Several interrelated themes run consistently through his research and teaching: the importance of artifacts in human life, the necessity of studying relationships among people and artifacts, and the relevance of archaeological method and theory to addressing societal problems. With J. Jefferson Reid and Michael B. Schiffer, he cofounded behavioral archaeology, which prioritized the study of people-artifact interactions in all times and all places, from both historical and scientific perspectives. Behavioral archaeology, under the impetus he furnished, continues to develop new ways to research the material world.

Rathje was a phenomenally popular undergraduate teacher renowned for lively storytelling, a charming sense of humor, making any aspect of archaeology exciting, and using pithy examples to highlight the many contributions that the discipline can make to an understanding of behavior in modern societies. Although he chaired few dissertation committees, he exerted a profound influence on countless generations of Arizona graduate students, many of whom worked on the Garbage Project or were his teaching assistants.

Rathje's range of interests was breathtaking, as indicated by the many dozens of articles he published in popular archaeology and science magazines, which always melded archaeological insights to issues in contemporary society. It helped that he was an uncommonly good writer, a crafter of sparkling prose; he was also an artist who worked in several media. A kind and generous man, Rathje was one of American archaeology's most creative, prolific, and influential scholars.

Recent Advances in the Archaeology of the Southern Proto-Jê People

Rafael Corteletti[1] and José Iriarte[2]
[1]Departamento de Antropologia e Arqueologia, Instituto de Ciências Humanas, Universidade Federal de Pelotas, Pelotas, Rio Grande do Sul, Brazil
[2]Department of Archaeology, College of Humanities, University of Exeter, Exeter, UK

State of Knowledge and Current Debates

Introduction

The archaeology of southern proto-Jê groups dates back to c. 2220 cal year BP and extends to the beginning of the nineteenth century. It is mainly characterized by its diagnostic small ceramics with thin walls, the construction of earthworks (including pit houses and elaborated mound and enclosure complexes) in the highlands, plus collective burials in caves, and rock art (e.g., Schmitz et al. 1988; Beber 2005; Noelli 2005; Araújo 2007; De Masi 2009; Iriarte et al. 2008; Riris and Corteletti 2015). Recent works by archaeologists, anthropologists, and historians are emphasizing the historical continuity between the Taquara/Itararé Tradition (term used to refer to this archaeological tradition, cf. Beber 2005) and the southern Jê historic groups. We also use the prefix "proto" to encompass all the ancestors of modern southern Jê people in this tradition, including the former speakers of the extinct southern Jê languages (cf. Jolkesky 2010). Beyond the general label of southern proto-Jê and its shared material culture, there is increasing recognition that this broadly defined tradition spreads over a vast and diverse ecological area, encompassing a remarkable range of local variability in social and ritual organization (Fig. 1).

Archaeological projects during the last two decades have begun to reveal some general chronological trends in the development of the southern proto-Jê people. As shown in Fig. 2, the available radiocarbon dates indicate that Taquara/Itararé sites began to spread in the second millennium before the present, becoming more common around 1500 cal year BP and peaking after around 1000 cal year BP. Around 1000 cal year BP, we also see the appearance of mound and enclosure complexes and oversized pit houses (Copé 2006; Corteletti 2012; Iriarte et al. 2008; Schmitz et al. 2013a); significantly, this appearance coincides with the expansion of *Araucaria angustifolia* (Paraná pine) forest, as evidenced by pollen records along the southern Brazilian highlands (Iriarte and Behling 2007; Gessert et al. 2011).

The Southern Proto-Jê Emergent Social Complexity

Recent advances in the archaeology of southern proto-Jê people are the result of reanalyses of old data combined with the intense production of new data for the region. This work is showing that the southern Brazilian highlands were a highly structured landscape revolving around funerary/ceremonial mound and causewayed enclosure complexes, usually located on hilltops or ridges commanding wide views. Although the southern proto-Jê groups were established in the highlands for 2000 years, it was only in the latter half of this period that they started building mound and enclosure complexes as a novel form of funerary architecture (de Souza et al. 2016a). Locally called *danceiros* (dance grounds) in Brazil, these monuments are characterized by circular, elliptical, rectangular, and keyhole-shaped earthworks whose rims are 30–80 cm tall, 3–6 m wide, and 20–180 m in diameter. They may exhibit or lack mounds and associated ringlets. Mounds are generally circular but can be rectangular platforms (De Masi 2009); isolated large flat top platforms have been documented around São José do Cerrito (Schmitz et al. 2013a), Lages, and Campo Belo do Sul localities (Corteletti et al. 2016) (Figs. 3 and 4).

One of the most interesting aspects of the research on southern proto-Jê mound and enclosure complexes is that they reveal a clear connection between the archaeological record and ethnography. In fact, the southern Brazilian

Recent Advances in the Archaeology of the Southern Proto-Jê People, Fig. 1 Southern proto-Jê territory on Paraná River basin. (By Jonas Gregório de Souza, 2016)

highlands is one of the few regions in the world where mortuary rituals associated with mound-building are recorded in the European accounts of the seventeenth to nineteenth centuries. The southern Jê groups were subsequently investigated by ethnographers during the twentieth and early twenty-first centuries (Becker 1976, 1999; Crépeau 1994; Veiga 2006, as examples of syntheses). These groups exhibit dual social organization characterized by exogamic, patrilineal moieties. In the case of the Kaingang, the moieties are complementary but also asymmetrical; the archaeological and ethnohistoric records suggest the presence of sizeable, regionally organized, hierarchical societies (e.g., Crépeau 1994; Fernandes 2000). Importantly, funerary and post-funerary rituals are reported to be their single most important ceremony, when the entire group gathered together showing their dual organization. These events included the burial of important chiefs, secondary burials, the inheritance of the chiefly office by the eldest son of the deceased chief, initiation rites, name-giving ceremonies, performance and re-creation of the cosmogony myth, and feasting (Silva 2001; Veiga 2006).

In some regions mound and enclosure complexes occur together in groups. Their distribution in the landscape indicates that they are located on the top of prominent hills that today exhibit wide viewsheds (Iriarte et al. 2013). However, this is not always the case; these funerary structures can also be found in lower positions in the landscape, such as in the Urubici region (Corteletti 2012). As for the function of each category size of earthwork, Saldanha (2008) interpreted the small mound and enclosure complexes as likely village

Recent Advances in the Archaeology of the Southern Proto-Jê People, Fig. 2 Relation between vegetation history and culture history. (Source: Iriarte et al. 2017)

cemeteries. De Souza and Copé (2011) interpret small paired mound and enclosure complexes as low-level integrative facilities built and visited by the inhabitants of nearby pit house villages. At these sites, the village inhabitants undertook the interment of secondary inhumations and participated in collective funerary rites, reinforcing community ties. By contrast, large mound and enclosure complexes are interpreted as high-level social interaction facilities, whose construction involved the mobilization of labor from different communities dispersed across the region. More recently, Iriarte et al. (2013), drawing on the complementary asymmetry of historic Kaingang moieties, have suggested that the ritual separation of space in southern proto-Jê small paired funerary structures, characterized by a larger mound and enclosure complex on the west side, may be representing this dual ranked opposition.

The excavation of such burial mounds and the analysis of the cremated human remains within them has also begun to reveal a diversity of funerary practices, including the cremation and burial of single or multiple individuals within pyres with the subsequent redeposition of cremated bone (Müller and Mendonça de Souza 2011; Ulguim

Recent Advances in the Archaeology of the Southern Proto-Jê People, Fig. 3 Excavation in progress at Abreu and Garcia mound and enclosure complexes, Campo Belo do Sul, Santa Catarina, and the wide landscape view. (Picture: Rafael Corteletti 2014)

Recent Advances in the Archaeology of the Southern Proto-Jê People, Fig. 4 Passo Fundo 1 flat top platform, Lages, Santa Catarina (Picture: Rafael Corteletti 2011)

2015). Remnants of funerary pyres containing burned bones have been found at the base of the mounds (De Masi 2009; De Souza and Copé 2011; Müller and Mendonça de Souza 2011). Redeposition of burned bone in "cremated deposits" is also common, both in small pits and on mound floors (Thompson and Ulguim 2016). Sometimes these practices are present within the same mound. In addition, patches of burnt earth with a few charcoal fragments have been identified at mounds, suggesting that these could be the pyre-bases and ash-beds of pyres where all the burned bone has been gleaned and redeposited at another mound (De Masi 2009; Iriarte et al. 2013). Finds of small ceramic cups are characteristically associated with the interments and possibly indicate food offerings. Despite the fragmented nature of the burned bones recovered in the excavations, aging evidence from the unfused distal tibial epiphysis indicates a probable subadult of 14–20 years old at the burial cut feature of RS-PE-29. At the SC-AG-108 site, evidence for dental eruption indicates an age of greater than 21 years (Ulguim 2015). The types of fractures on the bones suggest that bodies were cremated with soft tissues and that fire temperatures may have exceeded 650 °C (Müller and Mendonça de Souza 2011).

In summary, this monumental funerary architecture may be the best example of how new traditions may have been born out as a result of the multiethnic interactions that took place during the late Holocene. By synthesizing the dates and locations of all known mound and enclosure complexes in the highlands, De Souza et al. (2016a) have proposed that they emerged in a period when the Guarani groups started to advance up toward the highlands and that they only proliferated in areas where the local groups did not interact with the outsiders. De Souza et al. (2016a) argue that the construction of chiefly burial mounds represented a form of smart advertising to keep outsiders out; they were a key element in the regional integration of the southern proto-Jê groups, undertaken in order to resist the Guarani migrants. The mound and enclosure complexes from the first half of the second millennium AD, and the circumstances in which they arose, are very different from the ones reported during the seventeenth to twentieth centuries. However, there appear to be many subjacent structures associated with the asymmetrical dual organization of Jê societies and with the spatial segregation of ritual space and the alignment of burial mound and enclosures that endure during historic times (Iriarte et al. 2013).

Community patterns are also beginning to play an important role in understanding the nature of settlement patterns in the region. In the southern Brazilian highlands, pit house villages of the southern proto-Jê groups are beginning to be seen in a new light. Recently, detailed topographical mapping, tailored to reveal community patterns, has brought dividends in terms of the reinterpretation of these sites (see Iriarte et al. 2013 for details). The settlements themselves could also be defined by artificial low terraces on their downhill slopes (Fig. 5). Similarly, as new

Recent Advances in the Archaeology of the Southern Proto-Jê People, Fig. 5 The oversized pit House 1 at Baggio 1 site, Campo Belo do Sul, Santa Catarina. (Picture: Rafael Corteletti 2015)

large pit house villages are beginning to be mapped in their entirety, new spatial patterns are becoming apparent. For example, at the São José do Cerrito locality, site SC-CL-70/71 exhibits 107 pit houses in two groups of 39 and 68 subterranean structures. The larger group of houses is organized in discrete clusters and accompanied by a cluster of ten mounds. In particular, small clusters of houses have a linear, U-shape or semicircular layout and in one case surround a large mound (Schmitz et al. 2013b). In the Urubici region, Corteletti (2012) mapped cluster of sites approximately 5 km distant from each other along the Canoas river valley suggesting community patterns of the landscape use. These sets of sites include pit house villages, surface sites, mounds and enclosures complexes, rock-shelters with burials, and rock art sites suggesting each cluster may represent a different community (Fig. 6).

As well as these villages with a large number of pit houses and well-planned arrangements, the oversized pit houses are worthy of notice. These structures have diameters of up to 20 m and, in one case, over 25 m and depths that may reach 7 m (Copé 2006; Reis 2007; Schmitz et al. 2010, 2013a). Although they may be isolated, oversized pit houses may also form part of clusters where they are surrounded by smaller pits; they are often accompanied by large mounds (Schmitz et al. 1988; Copé 2006; De Souza et al. 2016b). It is not yet clear whether these structures represent habitations of extended families, high-status individuals, or communal facilities similar to men's

Recent Advances in the Archaeology of the Southern Proto-Jê People, Fig. 6 Kernel density map of one cluster of sites placed at upper Canoas valley, Urubici, Santa Catarina. (Source: Adapted from Corteletti 2012)

houses and *kivas*. Some appear to have been regularly kept clean, with high densities of ceramics deposited in adjacent midden refuse areas outside the house (Schmitz et al. 2002), whereas others revealed semicircles of hearths and associated activity areas around the center, suggestive of many nuclear families or different groups in a gathering place (Copé 2006). What is certain is that the large scale of these structures and the labor organization and effort necessary for their construction marks them apart from the other domestic sites. For example, De Souza et al. (2016b) conducted a program of comprehensive AMS radiocarbon dating and Bayesian modelling at the deeply stratified oversized pit House 1, at Baggio I site (cal. AD 1395–1650), in Campo Belo do Sul. The stratigraphy revealed a sequence of 12 well-preserved floors, including 5 completely burnt collapsed roofs, evidencing a major change in occupation dynamics (Fig. 7). The results of the radiocarbon dating allowed for an understanding of the occupation dynamics of an oversized pit house, demonstrating it was occupied for over two centuries with no evidence of major periods of abandonment. In addition, the House 1 sequence allowed transformations in ceramic style and lithic technology to be tied in to an absolute chronology, providing new evidence that the emergence of oversized domestic structures is a relatively recent phenomenon among the southern proto-Jê. As monumental pit houses started to be built, small pit houses continued to be inhabited, evidencing emerging disparities in domestic architecture after AD 1000.

In addition, the application of microfossil botanical techniques is changing our view of the diet of these groups and illuminating particular aspects of ritual behavior carried out in mound and enclosure complexes. For example, recent combined phytolith and starch grains residue analysis on ceramic fragments from the Bonin site in Urubici has documented for the first time the consumption of manioc (*Manihot esculenta* Crantz), beans (*Phaseolus* sp.), and possibly yams (cf. *Dioscorea* sp.), in addition to maize (*Zea mays* L.) and squash (*Cucurbita* sp.) (Corteletti et al. 2015). These results confirm that southern proto-Jê subsistence was based on a variety of plant foods and that the people were practicing food production from at least the thirteenth century. These data confirm the paleoecological records and allow us to suggest a new model of mobility, in which food production may have allowed populations to settle in the southern Brazilian highland plateau year-round (see Corteletti et al. 2015 for details).

The Southern Proto-Jê Built Landscape

Archaeologists and paleoecologists are investigating the different roles played by climate and humans in the changing landscapes of the late Holocene in the region, as evidenced by pollen and charcoal records (Bitencourt and Krauspenhar 2006; Iriarte and Behling 2007). The southern Brazilian highlands witnessed an increase in habitation sites around the turn of the first millennium AD, along with the arrival of mortuary/ceremonial architecture and oversize pit houses in the highlands and the development of patches of dark anthropogenic soils in the Atlantic rainforest escarpment. At the same time, Jê funerary patterns also began to appear along the coast (DeBlasis et al. 2014). Significantly, these cultural changes are broadly contemporaneous with the abrupt expansion of *Araucaria* forest, which according to some records (Behling et al. 2007) replaced high altitude grasslands within about 100 years. The rapidity and timing of this process raises the possibility of an anthropogenic cause (Bitencourt and Krauspenhar 2006; Iriarte and Behling 2007; Dos Reis et al. 2014). Previous paleoecological work has generally interpreted these abrupt changes as a response to increased precipitation (e.g., Behling et al. 2007). However, the human footprint in the expansion of the Paraná pine forest should be seriously considered. Paraná pine nuts were a major dietary staple of these pre-Columbian cultures; historically, regional chiefs had territorial control over Paraná pine forest patches, with collective feasts being held during the time of food abundance when the nuts were ripening. One can speculate that this abundant and reliable resource may underlie the increase in archaeological sites and may have been integral to the emergence of social complexity. It is therefore conceivable that the expansion of Paraná pine occurred not because of climate change but as a result of human activity promoting the expansion of this economically important food resource (Fig. 8).

However, it has not yet been possible properly to assess the relative influences of humans versus climate change in driving this *Araucaria* forest expansion, for the following reasons: (i) most vegetation reconstructions have insufficient chronological resolution; (ii) most cores have been retrieved from bogs/lakes far away from archaeological sites (Behling et al. 2007); and (iii) there are very few paleo-vegetation reconstructions. As a result, until now it has not been possible to determine the environmental characteristics of either the local or regional Jê settlements or their development, vis-a-vis the transformation and possible anthropization of the southern plateau environments. However,

Recent Advances in the Archaeology of the Southern Proto-Jê People, Fig. 8 *Araucaria* forest and the upper Canoas valley visibility from Urubici 20 pit house village, Urubici, Santa Catarina. (Picture: Rafael Corteletti 2010)

current archaeological and paleoecological research is being carried out to clarify all these patterns (Cárdenas et al. 2015; Corteletti et al. 2016). The potential manipulation of mixed *Araucaria* forest in the southern Brazilian highlands may not have been exclusively restricted to *Araucaria*; current studies are investigating the possible management of *goiabeira-serrana* (*Acca sellowiana*) (Santos et al. 2005), among other important economic plants and fruits, by integrating botany, genetics, and archaeology.

Final Considerations

In conclusion, the southern Brazilian highlands represent one of the most promising research areas in South America in which to investigate scenarios of social change concomitant with major transformations in the landscape. What is becoming increasingly clear is that the marked expansion of the resource-rich *Araucaria* forest at the turn of the second millennium AD was accompanied by novel social developments among the southern proto-Jê groups. The most evident of these is the rise of a new funerary tradition, represented by the mound and enclosure complexes, where a few cremated burials were likely commemorated with events of feasting. Parallel to that, we witness the emergence of aggregated well-planned villages, with evidence of a long duration of use and sometimes with notable disparities in pit house size. Some villages include centrally placed oversized pit houses, with diameters that may reach over 20 m, as well as mounded architecture. Management of the *Araucaria* forest, coupled with a more intense cultivation of domesticated plants, might have provided the basis for the mortuary feasting events at mound and enclosure complexes, as well as leading to increased population density and territoriality and the emergence of disparities in house size. These processes potentially relate to the foundations of political complexity among the southern proto-Jê groups and to the formation of the regionally organized, hierarchical societies documented in the southern Brazilian highlands during the historical period.

Recording in Archaeology

Madeleine Hummler
Department of Archaeology, University of York, York, UK

Introduction and Definition

Archaeological field work is a scientific process that relies on recorded observations and measurement. It is accepted that the archaeological record is not an exhaustive rendering of the site, even though it may represent much of what is left of it. However, every anomaly recognized in the field must be given a location and a description, since without these no analyses or interpretations are possible. Comprehensive recording has become the guiding principle of archaeological survey and excavation, especially where a site is to be destroyed, since the record has to stand as a proxy for the site itself.

A multitude of factors, including the circumstances of deposition (intentional and unintentional in the past), site formation processes and postdepositional activity, terrain and types of remains, and the techniques available, determine what is or could be recorded. We can only record what we know how to detect, something that is in constant evolution, with new research alerting us to fruitful avenues of enquiry. A relatively recent example is the recording of significant chemical traces in floor areas, even though we cannot "see" them (see Carver 2011: 49–56 for an introduction to some of these techniques).

Key Issues, Current Debates, Future Directions, Examples

Recorders strive to strike a balance between measured and intuitive observation, as may be seen in the growing literature on archaeological practice, for example, the essays on practices from the seventeenth to the twentieth century in northwestern Europe (Wolfhechel Jensen 2012), or the discussion by Lucas (2012: 18–73) of philosophies of recording, including different stances on "total" or "selective" recording exemplified by Pitt Rivers and Petrie in later nineteenth- and early twentieth-century Britain and Egypt (Pitt Rivers 1887 cited in Lucas 2012: 45–51). General Pitt Rivers insisted that "every detail should [. . .] be recorded in the manner most conducive to facility of reference" (Pitt Rivers 1887 cited in Lucas 2012: 45), but he was by no means the only one or the first to adopt this stance. Modern archaeological historiography is writing a more varied and less linear account of field experience and precept, for example, the very detailed instructions in 1836–1837 for excavations of barrows in Mecklenburg (Germany) by Friedrich Lisch (Eberhardt in Wolfhechel Jensen 2012: 154–6). Similarly, the emergence of open area excavation has been claimed by many different traditions (Germany and Britain in the 1930s; Denmark in the 1930s; Soviet settlement archaeology in the 1920s–1940s influencing Leroi Gourhan's *grands décapages* of the 1960s).

Recent decades have seen growing criticism of the position that recording can be wholly objective. Reynolds and Barber (1984: 97) noted that "the emphasis on recording technique has been [. . .] an attempt to convert the whole site, lock, stock and barrel, into a physical record. In effect, this too often means that observation (an essentially active process) gives place to passive mechanical recording." For Hodder "The key point is that excavation method, data collection and data recording all depend on interpretation. Interpretation occurs at the trowel's edge" (1997: 693). Lucas's concept that the archaeological record is an *act of translation* (2012: 237–8) is helpful: translating the physical reality of what is

in the ground, transferring it into another medium, giving it meaning, and accepting that interpretation is part of the equation. If recording is translation, then the tension between subjectivity and objectivity becomes a positive force.

Recording in Four Acts

So, records must be made, but which records? Introductions to archaeology and textbooks on archaeological practice give primacy to written, drawn, and photographic records (physical or digital) and the definition and recording of sampled materials, and there is much agreement on procedures. A useful way of thinking about the archaeological record – rather than structure it into written, drawn, and photographic records – is to divide it into four *purposes*: recording *location* (position, geometry, distribution), recording the properties of *elements that are observed but not kept* (strata, stratigraphy), recording *elements that are kept* ("finds" including biota, samples), and *monitoring* (recording what has been recorded, how, and why). The summary that follows will be limited to reflections drawn from experience and from literature dealing with archaeological practice, especially on excavation (e.g., Roskams 2001; Carver 2009; Tassie and Owens 2010). Surface and subsurface surveys make use of some of these procedures (e.g., to record location), although they have their own strategies (e.g., for levels of coverage) and dedicated protocols and software not detailed further here.

Location

The principle of locating a point on the ground is to position it on a horizontal *grid* using an easting and northing (x and y coordinates) and to measure its height above a datum point, for example, sea level (z coordinate). The three-dimensional Cartesian coordinates (x, y, z) give a unique *map reference* relative to the rest of the known world. This can be measured with tapes and compass, with a square and level, with a Total Station Theodolite (TST), or with a Global Positioning System (GPS), depending on the resources available and the accuracy required (TST being the most desirable but fairly expensive) (Tassie and Owens 2010: Chapters 2 and 6). The speed and accuracy of electronic measurement can lead to a more mechanistic and paradoxically more interpretative way of recording site geometry, such as deciding where the outline of a layer lies and just plotting points along it rather than drawing detailed surface plans with planning frames (of course combinations of methods can be used or supplemented, e.g., by photography). Location records produce *maps* (showing sites and areas), *plans* (showing individual contexts, features, and structures), *plots* (showing the distribution of objects) and *sections* (vertical record of deposits). Maps, plans, and plots may be generated digitally on site using basic computer graphics programs.

Recording What Is Not Kept

Let us take a flint tool (an *artifact*) found in a layer (a *context* or stratigraphic unit). The artifact will be kept (see below), but it lies in soil (the context) that will be discarded or sampled, and has a physical, spatial, and stratigraphic relationship that can only be recorded on a unique occasion (when it is lifted) in written, drawn, and photographic form. Not surprisingly the burden of recording what cannot be kept lies heaviest on the recorder and has generated the most print on how to do it, such as Harris' principles of archaeological stratigraphy (whose application is explained in Roskams 2001: Chapters 9 and 11–13); how to record individual stratigraphic units (e.g., in the Museum of London Archaeology Service [MoLAS] (1994) manual and in countless textbooks); or how to capture graphic and photographic data in many ingenious ways (e.g., *Antiquity*'s online Project Gallery, http://php.york.ac.uk/org/antiquity/projgall.php, has published in 2011–2012 papers on real-time 3D field recording in southern Jordan, or photogrammetry for recording archaeological structures on the Upper Tigris).

The development of the definition of basic stratigraphic units (contexts) has been widespread and parallel; it is attributed, for example, to Britain in the 1970s, Sweden in the 1960s (Ambrosiani in Wolfhechel Jensen 2012: 312), or Poland in the 1940s. In excavation, the *context* is the deposit of material that we define as being different from another, in terms of composition, shape, and

stratigraphic position. A context does not have to be a layer of soil only, it can be the stones making up a wall (its mortar would be another context). Contexts are not givens (*data*), they are entities that we define (*capta* as they have been called), and therefore, we can also assign a context number to an *arbitrary layer* (or spit). Since contexts are defined, it follows that a cut into the soil (for a feature like a pit) can also be a context (it differs in shape and stratigraphic position from other contexts). *Single-context recording* (see Roskams 2001) focuses on these entities, without features and structures recorded in additional forms (see below).

As well as its location and shape, a context record includes a description of its material: something that has become standardized in the interests of analytical potential. Lucas (2012: 87) gives a typical example: "compact mid greyish brown sandy silt with occasional inclusions of fine charcoal (2%, <5 mm) and subangular gravel (1%, <10 mm) [etc.]" and laments the fact that the interpretation of this piece of soil is a laconic "pit fill." Indeed too much attention appears to be paid to the composition of strata and the geometry of the feature and too little to the human agency behind it (the "pitness" of a pit). It also seems that much of this descriptive detail has little analytical purpose, except perhaps analyses of the presence/absence of charcoal or of Munsell soil colors. This is not to say that we should stop recording context composition, but should look for more analytical outcomes, to match the discoveries of microstratigraphy and micromorphology (Carver 2011: Chapters 2) (Fig. 1).

The need for higher-level interpretations made on site, such as the recognition and study of a pit, a hearth, or a wall, has been met by the formal definition of groups of associated contexts, known in Britain and the USA as *features*. The nature of the feature (also confusingly called master context, locus, structure, group, set, complex, *Befundkomplex*, or *fait*) is well established and a helpful definition is given by Py (1997: 30): "if the context is the atom, the feature is the molecule." Examples of forms devised to record features are given in Carver (2009) and Pavel (2010), the latter a valuable collection and commentary of 60 different systems (all illustrated) used for recording on excavations in Europe, America, and the Near East. By the same token, sets of associated features may merit a site record at an even higher level of interpretation in the form of a *structure*, for example, a building formed by a regular pattern of postholes (Carver 2009: 138–46).

Recording What Is Kept

That artifacts and ecofacts are recorded and kept seems self-evident, but when we consider how

Recording in Archaeology, Fig. 1 Recorder at work, showing context record sheets (*right*), feature record sheet (under the tape), drawing (on the knee), and Munsell color chart (*center*) (M. Carver)

small and even "invisible" these can be, it becomes apparent that choices are being made and what is recovered is only a sample of the whole. At one extreme, on sites with huge amounts of pottery (e.g., at Lattes in southern France), it may be that we record the presence of body sherds of dolia with reference to a typological scheme, but do not keep them all. At the other end of the scale, minute fungal spores would only be found if we took samples of soils in which they survived. In general the trend has been to increase the amount that is recorded, because our perceptions of what is important have changed: excavators of the La Tène inhumations at Münsingen-Rain in Switzerland in the early 1900s kept only the skulls. By contrast the advent of routine sieving and flotation in the later twentieth century has vastly increased our knowledge of the environment and economy through the recovery of fish and small mammal bones or insect and vegetable matter. It follows that a consistent sampling strategy with an analytical purpose is needed. Indeed it would be futile and unmanageable to take 10-l bulk samples of every context just in case there was something there. We need to set out the degree of sampling, processing, analysis, and storage that is intended: for example, what percentage of what type of deposit is dry or wet sieved, put through flotation, or taken for specific purposes. Helpful tables of such purposes can be found in Carver (2009: Chapters 8 and 9) and in Tassie and Owens (2010: Chapter 4, Tables 4 and 9–14). It goes without saying that consistency is important, as it would be pointless to compare in analysis deposits that were similar (e.g., fills of storage pits) but which were treated differently (e.g., some excavated summarily, others treated with full recording and comprehensibly sampled). Obvious as this is, this need for consistency has implications for the recovery levels (see below) deployed on excavations.

Monitoring

As important as recording the stuff on site is recording the recording: what was done, not done, decided, discussed, and interpreted. In short, monitoring, which also includes the metadata (the documentation generated to keep track of what has been recorded, such as numerous indexes). So, in addition to the proformae used on site, a *site notebook* is an essential tool, to record the day-to-day running of the site, evolving ideas, and changes in strategy, in short all the things that are not accommodated in standard forms but which inform the outcome of the excavation. That outcome is dependent on the decisions taken about how to treat different parts of the site; indeed we dig and record at different levels of intensity, for example, removing the topsoil by machine, shoveling rubble, or carefully excavating a skeleton. Most recording proformae have boxes to record the levels at which individual contexts and features have been excavated and recorded, but this can be done more efficiently by referring to a structured scheme, such as *recovery levels*. There are obvious advantages to adopting a recovery level structure – it formalizes procedure and promotes consistency but also allows flexibility. However, that very flexibility has its dangers: having a recovery level scheme should not give license to implement arbitrary "gear changes" (e.g., "we decided to treat this deposit at level B rather than level D because we were pushed for time"). It is therefore important to stick to the recovery levels, once a project design has been agreed, so that like can be compared with like in analysis.

The records generated inform analysis and publication but they also exist for future generations to interrogate. Therefore, they need to be deposited in permanent archives and made easy to consult. Archives typically contain not only the "raw" data and the metadata in physical and electronic form but also the documentation pertaining to the conduct of the project and its analysis up to publication. How this is achieved will vary from country to country, as will the form of storage, whether as a physical archive or electronically; examples of pioneering digital systems can be found for Lattes in France (Py 1997) and in Britain an early example of an integrated archive was presented by Powlesland in 1998 (articles in *Internet Archaeology* 5). Good advice on archives in general, derived from the British experience, will be found in Brown (2007).

Prospect

To sum up, archaeological recorders are objective, subjective, consistent, selective, accountable, and creative all at once. There is no universal prescription, but there is a consensus that location, stratigraphy, composition, monitoring, and archiving underpin recording systems. Whether devised or adopted ready-made (you can, e.g., download the MoLAS manual, or the recording forms from a CD in Tassie and Owens 2010), this is only the beginning: systems should not be set in stone; they can be adapted to suit new analytical purposes. In this way the sophisticated investigations of the future will be integrated with the basics recorded now. Stratigraphic units will become more exciting: the tedious and analytically underexploited "loosely compacted 7.5YR 6/4 silty sand with occasional subangular gravel" will become the container of much more information: perhaps about tethered cattle which stood there chewing the cud (from chemical residues in a context stratigraphically later than another, which was a secondary deposit derived from a midden containing protein residues from fish processing). To contribute to documenting a (purely hypothetical) change from hunter-fisher-gatherers to an economy based on domesticates is not a bad aim for the hard-pressed recorder struggling in the wind and rain.

Red Sea: Maritime Archaeology

Lucy Blue
Centre for Maritime Archaeology, University of Southampton, Southampton, UK

Introduction

The Red Sea extends over 1,900 km in length and is one of the youngest seas on the planet (Fig. 1). Despite its arid and inhospitable desert coastline,

Red Sea: Maritime Archaeology, Fig. 1 Map of the Red Sea indicating the location of sites referred to in the text. (Produced by J. Whitewright)

it has been an important highway for maritime trade and shipping since antiquity. The Red Sea has a negligible tidal range (max. 90 cm) but is dominated by fierce and persistent NNW winds, particularly in the northern reaches (Whitewright 2007).

The earliest evidence of maritime activity in the region dates to the Middle Stone Age some 125,000 years ago, when early modern humans (*Homo sapiens*) first settled in the coast of the Buri Peninsula, modern Eritrea, fueling theories of Paleolithic maritime migrations out of Africa (Bailey and Flemming 2008).

In the Pharaonic era, tomb reliefs and texts reference maritime voyages that were conducted down the Red Sea to the mythical land of "Punt" (Kitchen 2009) to acquire frankincense and other exotic commodities. Finds dating to the Old, Middle, and New Kingdom excavated from storage galleries at the sites of Wadi Gawasis (Bard and Fattovich 2007: 135–163; Ward and Zazarro 2010) and Wadi el-Jarf (Tallet 2012) further to

the north extend knowledge of this trade and also reveal elements of ship's rigging and planking. A 280-m-long mole was also discovered at the site of Wadi el-Jarf, which together with the charred remains of Twelfth and Thirteenth Dynasty ship's timbers discovered at the site of Ayn Soukhna on the Gulf of Suez in the Sinai (El-Raziq et al. 2006; Tallet 2012) further enhances our understanding of the Red Sea harbor and ship construction of the period, essentially planks secured by double, unpegged, mortise-and-tenon fastenings with intermittent stitching.

Key Issues/Current Debates/Future Directions/Examples

Trade and Ports

From the Greco-Roman period, we have a wealth of evidence in the form of texts such as the mid-first-century CE *Periplus Maris Erythraei* (Casson 1989) that describe voyages within the Red Sea and beyond to the Indian Ocean. Key to the maritime expansion of Indo-Roman trade were ports. Ports facilitated an interface between land and sea and acted as a conduit for the transfer and storage of goods. It would be no exaggeration to suggest that the sister ports of Myos Hormos and Berenice were Rome's gateway to the East. Strabo (*Geography* 2.5.12; Jones 1917–1932) indicated that over 120 ships sailed annually from the port of Myos Hormos. Both ports have been identified and partially excavated and provide valuable insight into the nature of maritime trade (Casson 1989; Peacock and Blue 2006, 2011; Sidebotham and Wendrich 2007; Tomber 2008).

Excavations in the former lagoon at Quseir al-Qadim, ancient Myos Hormos, revealed part of a late first-century BCE to early third-century CE Roman waterfront consisting of an amphorae wharf or jetty sealed by a trampled earth surface (Peacock and Blue 2011: 35–42; Fig. 2), while at Berenice a series of large coral block seawalls or quays were identified around the edges of the settlement, dating to the first century CE with one example toward the east of the site, dating to the fifth century CE (Sidebotham and Wendrich 1996, 1999). Additional ports along the Red Sea coast critical to Indo-Roman trade include Clysma, Aila, Ptolemais Theron, Adulis, and Muza (Casson 1989; Peacock and Blue 2007: 135–140).

Ports also reveal evidence for the nature of the ships that sailed the Red Sea during the Roman

Red Sea: Maritime Archaeology, Fig. 2 Myos Hormos – view of the Roman harbor amphorae foundation of the jetty "hard" in the silted lagoon (Produced by the Quseir al-Qadim Southampton University project)

period, including wooden planks secured by mortise-and-tenon fastenings some with in situ pegs (treenails) (Sidebotham and Wendrich 1999: 316; Peacock and Blue 2011: 179–210). Rigging components, including brail rings and several fragments of sailcloth, have also been recovered, the general form of which is consistent with vessels operating in the Mediterranean Sea during this period, although some materials were sourced in India (Wild and Wild 2001; Whitewright 2007; Peacock and Blue 2011: 179–210). A graffito of a Mediterranean style ship was also found at Berenice reinforcing the idea that Mediterranean style ships plied the Red Sea during this period (Sidebotham and Wendrich 1996: 315–317).

Shipwrecks

Limited shipwreck finds of all periods have been discovered in the Red Sea which is believed to be primarily due to the warm deep waters and coral-line environment (Blue et al. 2012). A number of wrecks dating to the Roman era have been investigated that support the terrestrial port data and textual evidence relating to Indo-Roman trade and ship construction. The Roman ship, referred to as the Fury Shoals wreck, has no visible signs of hull remains but consists of a cargo of Dressel 2–4 type amphorae that date the wreck to the first century CE (Fig. 3; Blue et al. 2012). Likewise, the exposed and heavily concreted site at Abu Fendera, located to the south of Berenice, reveals the visible remains of at least five different amphorae types, three two-armed stock iron anchors, and other metal artifacts, including lead hull sheathing that protected the hull from marine borers. The wreck at Abu Fendera was clearly a merchant vessel, and the hull sheathing and iron anchors suggest that it was built in the Mediterranean tradition. The collective shipwreck assemblage indicates that it dates to no earlier than the end of the first century CE and not later than the mid-third century CE (Blue et al. 2012). From the late fourth and early seventh century CE, a wreck was partially excavated off the island of Black Assarca, Eritrea. No hull remains were recovered, but the amphorae cargo has strong parallels with those produced in Aqaba during this period (Tomber 2008: 92).

Red Sea: Maritime Archaeology, Fig. 3 View of the Roman shipwreck of Fury Shoals. (Produced by the Southampton University/British Museum Red Sea Shipwreck Project)

Medieval Seafaring

The Red Sea was equally important to medieval shipping as it was to Indo-Roman trade, transporting trade goods and importantly pilgrims on route to Mecca through ports such as Al-Quseir, Aydhab, Suakin, and Jeddah. Direct knowledge of ships of the Islamic era in the Red Sea is limited to sewn planks recovered in a secondary context from Quseir al-Qadim that date between the late twelfth and early fifteenth centuries CE (Fig. 4; Peacock and Blue 2011: 179–210). They are one of the few examples of the distinguishing feature of ancient Arab craft of the Indian Ocean and the Red Sea, generally agreed to be constructed with "the use of fiber, rather than nails, to sew the planks of hulls together" (Casson 1989: 141; Hourani 1995).

The primary Islamic era shipwreck to have been excavated is a large Ottoman period vessel from Sadana Island, Safaga. Dating to the second half of the eighteenth century, the ship is thought to have carried up to 900 ton of cargo. Over 3,500

Red Sea: Maritime Archaeology, Fig. 4 Sewn Medieval planks from Quseir al-Qadim. (Produced by the Quseir al-Qadim Southampton University project)

artifacts were recovered, about one third of which was Chinese porcelain. Despite the nature of the cargo, the excavators believe that the ship was a local vessel possibly Egyptian in origin. Little data on the hull construction has been published, although the vessel is secured with iron fittings rather than being sewn (Ward 2001). Recent discoveries off the Saudi Arabian coast at Umm Lajj by a joint Saudi-Italian team have discovered and commenced excavation of another eighteenth-century shipwreck (Zazarro and Loreto 2017).

Conclusion

This short entry has attempted to summarize what is known to date of the maritime archaeological record of the Red Sea. Unfortunately, the current archive does not constitute a reliable shipwreck database and has limited iconographic representations of boats, and the documentary evidence is restricted to comments from ancient travelers and sailor's guides (Casson 1989). As such, there is much more to be discovered about this critical sea that provided a link between the Indian Ocean and the Mediterranean and that supported maritime activities for thousands of years.

Reflexive Approaches in Archaeology, Development of

Åsa Berggren
Department of Archaeology and Ancient History, Lund University, Lund, Sweden

Introduction

Although many researchers in archaeology would agree that there has always been an element of reflexivity in archaeological interpretation, calls for an explicit and systematized reflexivity within archaeology are rather recent (e.g., Potter 1991; Shanks and Tilley 1992; Hodder 1997). These may be regarded as part of a trend, in which archaeology is viewed within an ethnographic perspective and the objects of study are archaeological practices (Edgeworth 2006). The calls for reflexive methods may also be seen as an attempt to bridge the gap between archaeological theory and practice, thereby bringing into focus archaeological field practices and interpretation processes. There have been a few explicit attempts to systematize reflexivity as well as many implicitly reflexive studies in archaeology in recent years. In the following section, case studies that attempted reflexive approaches during archaeological fieldwork are explored.

Definition

Like being reflected in a mirror, to be reflexive is to have something directed back on oneself. The concept of reflexive archaeology is thus an archaeology directed back on itself. This means that the interpretation process and the production of archaeological knowledge are reflected on while in progress, by the person creating this knowledge. However, the reflection does not have to be directed back to the same person, as a reflexive approach may also be more generally applied within the field of archaeology.

Reflexivity has been discussed in fields such as sociology, ethnography, anthropology, and philosophy since the mid-1900s, and the term has been assigned various meanings. Sometimes these meanings overlap and even contradict each other. The different versions of reflexivity that have been in use have been divided into categories, ranging from a mechanical and descriptive to a more radical and interactive view of reflexivity. They include versions of reflexivity in which the observer's self-consciousness and self-criticism are in focus and in which the aim is to correct biases that distort the access to the object of study. They also include versions in which the observer takes a detached position which enables him or her to see through "taken for granted" in a society

and in which what you see is depending on your point of departure. The latter view rejects that an observer can step back from culturally laden prejudice and focuses on different standpoints, for example, gender or culture. There are also versions that attempt to produce alternatives to habitual thinking, as well as versions that regard reflexivity as a part of all communication. Most of these views on reflexivity presuppose a dichotomy between subject and object and aim at maximizing objectivity even though some may question this same objectivity (Lynch 2000).

The many different interpretations of the idea of reflexivity illustrate how the subject-object dichotomy underlies much of our thinking in Western research traditions and the implicit position that if we can reveal the circumstances of a study, there is a possibility to reach a more accurate account of the studied object.

Reflexive approaches have been employed and understood in different ways in the archaeological discipline in recent years. The definition used appears to be context dependent, and some would even argue that the idea of reflexivity has not yet been defined satisfactorily in archaeology (Chadwick 2003). However, what the different approaches seem to share is an ethnographical effort to investigate how the archaeological discipline itself including the archaeologists and the structure of work, methods, and tools influence the resulting images of the past.

A number of projects have attempted to explicitly define the term, and in this regard, two case studies will be explored in this entry. The first case study is the well-known Çatalhöyük – project in Turkey – which centers around archaeological investigations of a Neolithic settlement (Hodder 1997, 1999, 2000). In this project reflexivity is defined as an examination of the effects of archaeological assumptions and actions on the various communities involved in an archaeological process, including participants in the project as well as other archaeologists and non-archaeological communities (Hodder 1997, 1999, 2000). The project aimed to promote reflexivity and multivocality in the process of creating archaeological interpretations as well as situating the research within a social context. The methodology is built on two main ideas: (1) that archaeology does not produce objective facts and (2) that no interpretation should have preeminence over another. The individual excavator is emphasized as playing an important role in forming the interpretations, and the goal is to record this subjective trait. The field methods are, therefore, aimed at documenting what may influence the archaeological interpretations (e.g., the preconceptions and assumptions of the excavating staff). The underlying objective is to create a non-dichotomous way of thinking, which will ultimately break down barriers both between disciplines and between interpretation categories used in archaeology, such as different materials and features. The context in which archaeological knowledge is created is thus illuminated. This does not only extend to the archaeological field but also to the society as a whole as a variety of stakeholders and interest groups are considered (Hodder 1997, 1999, 2000).

Another project that has attempted to define reflexive approaches is the Citytunnel project in Malmö, Sweden. It was a large-scale project within a developer-funded archaeology context, and the fieldwork took place during the early 2000s. The project aimed at "documenting the documentation process," which was stated in the research design (Lindhé et al. 2001). This was later broken down to a few practical components, partly inspired by the Çatalhöyük project.

In the Citytunnel project, reflexivity was defined broadly as a continuously ongoing process that includes thoughts about one's own thinking and one's own role in the production of knowledge, drawing on a sociological framework (Ehn and Klein 1994). By documenting the interpretation process, it was hoped that the different stages of the thought process and the various preconceptions of the individual excavators would be illuminated. The aim was to allow multiple voices to be heard, as well as to enable a critical evaluation of habitually used categories and interpretations. In the end, the objective was to gain new perspectives that would lead to new questions and new knowledge about the past (Berggren 2002).

Another project investigating the landscape at Leskernick on Bodmin Moor in Great Britain also

employed a reflexive approach. This project took as a starting point the statement that archaeological interpretation is an ongoing and open process in which there are always other possibilities and multiple interpretations. The project positions itself against what are called standard archaeological texts which protect themselves from criticism by filtering out the manner in which some interpretations are preferred to others, by excluding the process by which we arrive at certain understandings (Bender et al. 2007: 28).

Historical Background

The development of reflexive approaches in archaeology has to be seen in the context of how archaeology as a field has developed during the past few decades.

A few early attempts of ethnographic approaches to archaeological work appeared in the 1950s and 1960s (see Edgeworth 2006 for a detailed background). These may be seen as the first attempts to apply an explicitly reflexive approach in archaeology. Earlier, archaeologists had written diaries and kept notes in a way that sometimes reflected on their work. However, this was not done in a systematic and explicit way, and they are not included in this discussion.

The attempts of an ethnography of archaeology seem to have ceased during the 1970s and early 1980s, probably as a result of the emphasis on scientific objectivity in the processual archaeology that was developed under the name New Archaeology (Edgeworth 2006: 2). At that time there was a notion of scientific neutrality and objectivity of an existing record in the ground, waiting to be unearthed and discovered (Lucas 2001a). This meant that the social, economic, and scientific circumstances of the archaeological recovery were considered unimportant to the formation of this record. Reflections concerning this formation were thus not seen as useful.

During the late 1980s and 1990s, this notion of scientific objectivity was challenged from a post-processual viewpoint in which interpretation was regarded as an essentially subjective process. Archaeological practices, especially archaeological fieldwork, were starting to be reevaluated, and excavation was no longer seen as a mechanical uncovering and recording of preexisting truths but rather a social and subjective construction of interpretations (e.g., Tilley 1989; Gero 1996; Hodder 1997).

The question of excavation being an objective or subjective undertaking is connected to a separation between data and interpretation in archaeology that can be followed over time. This is not just a theoretical issue but connected to the separation of theory from practice in archaeological fieldwork and of thinking from excavating (which in turn is connected to the separation of subject from object). It has been shown that this separation has developed over a long period of time and has a social basis. From very early on (before the increasing professionalization of the discipline), the excavation process was seen as unskilled and requiring little formal training, which resulted in a gap between the excavator and the interpretation. In later years excavators were required to follow strict positivistic techniques, which were to insure a scientific quality. Contract archaeology was seen as providing scholars at universities with data to be interpreted, rather than producing interpretations in the trench. The moment of discovery was thus separated from the moment of study and data from analysis and interpretation. The excavator was thus regarded as a provider rather than a producer of data (Berggren and Hodder 2003). The hierarchical organization of developer-funded archaeology (Lucas 2001b: 12; Rudebeck 2004), the prioritization of economical over archaeological goals in the private sector (Watson 1991; Hester et al. 1997), the invisibility of the excavator in the record (McFayden 1997 quoted in Lucas 2001b; Cooper et al. 2000), the mechanics of excavation (Chadwick 2003), as well as the standardization of recording (Adams 2000) are a few of the reasons mentioned for this separation. Also, in a research context, unskilled, local workmen or inexperienced students may be used.

There are thus many factors that have acted through time that may explain the separation of theory and practice within archaeological fieldwork. One factor that seems to be overarching is hierarchy. The hierarchical organization of excavations, of the labor market, and of society as a whole are all connected and influence the situation of the excavator. The separation of interpretation from fieldwork thus has deep societal roots.

Key Issues/Current Debates

The key issues relating to the development of reflexive approaches in archaeology are to be found in the historical background described above. It was a reaction to some of the problems mentioned and to what may have been experienced as contradicting trends in contemporary archaeology. These trends include demands for a more formalized and predictable research from authorities (mainly in developer-funded archaeology) and at the same time demands for a democratic and multivocal archaeology, as well as an increasing digitalization of the archaeological record that demands predefined categories and at the same time, therefore, requires a deconstruction of concepts and categories (Berggren 2002; Rudebeck 2004).

There are several characteristics that can be identified in the development of reflexive approaches. First, there was a need to question and problematize concepts and categories that had become so well used and familiar that they seemed axiomatic. Discussions of concepts and categories have always formed a part of the archaeological discourse. However, this kind of problematization became a more explicit part of the problem orientation of developer-funded archaeology, especially in the development of research designs. Secondly, there was also a need to create syntheses of interpretations within archaeology and in collaboration with other disciplines as well as with other groups in society. Syntheses of interpretations have always been an important component in archaeological research. However, in a reflexive approach, a synthesis of different views and research areas was aimed at from an initial stage of the investigation, influencing decisions of how work was to be conducted, e.g., quick feedback from specialist analyses of materials such as lithics of archaeobotanical material could influence the continuation of the excavation of a certain area or a certain category of remains. Thirdly, there was an increased interest in an ethnography of archaeology and the need to reflect on the role of individual archaeologists in the process of interpretation and the creation of archaeological knowledge, as well as the role of archaeology in society. This concerned both archaeological fieldwork and engagement in public outreach (Berggren 2002).

Reflexive approaches in archaeology were also a way of implementing the post-processual school of thought in practice, which had previously been primarily theoretical. The Çatalhöyük project became well known as a post-processual excavation where the somewhat abstract ideas were turned into practice in the system of work. At Çatalhöyük the excavation and recording methods were designed to solve the recognized problems. These methods have been outlined and elaborated in several publications since the inception of the project (Hodder 1997, 1999, 2000). The methods were designed to promote reflexivity, contextuality, interactivity, and multivocality. Steps towards these four goals were to be taken through a series of strategies that were included in a daily work on site. The strategies, as presented by the project director, included interaction in the field between the excavators and the specialists that were present on site. Such interaction included negotiations about the priorities of what should be investigated in the field and laboratory. The employment of this method was a clear attempt to break down barriers between people in the organization of work. Another strategy employed to promote reflexivity was the process of improving the contextualization of finds. A process of immediate feedback from the laboratories to the excavators in the field was introduced, a so-called fast track, to enable quick

analyses and results to influence the decisions being made in the field. An integrated database enabled different participants to take part in the flow of information as it was being formed. All these strategies attempted to integrate people and processes that are often kept separate during archaeological research. Another way of promoting reflexivity was a digital diary that was created to function as a key to the database. In it the field staff were asked to write about the excavation, their assumptions, decisions, and interpretations about particular features or finds. In this way the information in the database was to be situated in a broader context. This was meant to enhance the flow of information while at the same time providing the excavators with additional opportunities to reflect on their work. For the same reasons, short video clips of the excavation were also filmed. Anthropologists were also included in the project to work with the team, studying the construction of knowledge, visualization processes, as well as the impact of the excavation on the local community. To allow other stakeholders and interest groups to have access to the information being generated as a result of the excavations, the database was made public on the Internet. The above approaches thus allowed information to be accessed via multiple pathways. In this regard, it can be argued that the usual restrictions inherent in linear narratives (i.e., that keep data and interpretation separated) can be avoided or at least mitigated. Access to a virtual reconstruction of the site also enabled alternative readings of the information generated. Lastly, as the excavation was conducted by different national teams with different methods this also served to create different views of the site (Hodder 2000: 5ff) (Fig. 1).

After a few years of excavation, a reaction to these methods from the field staff was published (Farid 2000). The reflexive methods that had been implemented, however, did not always produce the desired outcome. In fact, some had been experienced as counterproductive. The demands on the field staff were considered to be imbalanced and one sided in that they were not considered specialists in their own right and were to be told what they were excavating by the laboratory specialists

Reflexive Approaches in Archaeology, Development of, Fig. 1 Excavation of the South Area of Çatalhöyük during the season of 2011. (Photo: Åsa Berggren)

(Farid 2000: 20). This caused some tensions between excavators and laboratory staff that were described as fault lines by one of the anthropologists who studied the creation of knowledge on site (Hamilton 2000). In fact, the field team felt new barriers were created between field staff and laboratory staff by the implementation of the methodology (Farid 2000: 28f). Other parts of the methodology required adjustments such as sampling strategies and the feedback about prioritized units. Generally the field team felt they had to keep a fine balance between time spent on the reflexive methods and time spent on excavating and recording, as the former were experienced as time-consuming additions to normal work (Farid 2000: 22).

Another fault line of the project identified by the anthropologist was created by the database. Its structure was in some ways experienced as restricting interaction between participants and reinforcing of categories instead on breaking

down the barriers between them. In addition the film clips were also considered problematic due to the fact that they were directed and thereby concealing the interpretative processes they were supposed to visualize (Hamilton 2000; also Farid 2000).

These difficulties took place during the initial seasons of the project. Indeed, it took some time for the reflexive methodology to be integrated in the normal work procedure on site. However, after some years, certain aspects were integrated, while others were more or less dropped (e.g., in the publication of the first years of excavation, the diaries are used and cited as a source of information in a way that visualizes the various excavators in quite an unusual way – see Hodder 2007). A study of diary entries written when the project was well under way (1996–2008) shows that the use of the diaries has varied over the years. It is concluded that the diaries provide a wealth of additional information not recorded elsewhere. However, the content of the diaries has changed and discussions about interpretations declined over time. Instead, the diaries became used as weekly reports by more experienced excavators and as blogs by students working on site. In general, the diary was mainly used by participants on a low level of the hierarchy of the project, e.g., the students. In addition, the entries were not read by other participants on site to any great extent (Boddington 2012).

Generally, the reflexive methodology at Çatalhöyük has had varying results. The many projects involving the local community as well as other interest groups within the Çatalhöyük project show that the aim of being multivocal has attracted much attention (not discussed further in this text). The implementation of the methods in field practices has failed in some respects but succeeded in others and is subject to further evaluation (Berggren and Nilsson Forthcoming).

In part inspired by the Çatalhöyük project, a large-scale attempt to introduce a systematized reflexivity in a developer-funded archaeology context was the Citytunnel project in Malmo, Sweden. While this project is similar in size to the Çatalhöyük project, there are many differences primarily due to the fact that the Citytunnel project is developer funded.

This project sets out to "document the documentation" (Lindhé et al. 2001). The idea was to integrate some ethnographic elements to the investigation. The ideas were turned into a few practical components such as digital diaries and film clips. In addition, 4 h per week per person were budgeted for digital diary writing and so-called why-meetings. The goal was to make these procedures a natural part of the work process (Fig. 2).

Reflexive Approaches in Archaeology, Development of, Fig. 2 Documentation of the remains of a Neolithic dolmen during the Citytunnel project (2002). (Photo: Markus Andersson)

As was the case with the Çatalhöyük project, the implementation of the reflexive methods was somewhat problematic. An evaluation of the project has been carried out (Berggren 2009), and it suggests that several factors affected the implementation. Factors such as "vague instructions" and lack of follow-up sessions are seen to have created negative impacts. The practical, reflexive components were experienced as either unnecessary or too abstract and detached from the usual work procedures. This was connected to opinions that work was already carried out in a reflexive way or that more specific instructions and goals were needed. The label "reflexive" gave the majority of field staff an impression of the attempt at something detached from usual work. In some cases it was experienced as a separation of something that had previously been a part of normal work which was now taken away and put in a box of its own, and in other cases, it seems to have resulted in an expectation of an almost magic formula that would automatically bring new results. Underlying these problems are complex issues of work hierarchies, the structure of work in developer-funded archaeology and individual motivation, among other things (Berggren 2009).

Other interesting results of the evaluation include an uneven representation of contributors to the diary as well as what was voiced. In practice the diary was dominated by a few opinionated male excavators that were not in positions to make decisions but rather executed decisions made by others. This pattern is similar to the Çatalhöyük project where students without authority were the most frequent contributors to the diary. The discussions were dominated by extraordinary finds rather than larger contexts and connections. Above all, the discussions in the diary did not reflect the importance given to issues in the research design nor in later publications. Thus, the diary was not used to any large extent during the process of writing up the material. This way the diaries give access to interpretation processes that are not visible in the publications such as the site reports (Berggren 2009).

The above case studies reveal that there are interesting results to be gained but also that there are problems connected to the implementation of reflexive methods in the practice of fieldwork. Even though only two case studies are discussed here, it is interesting to note that the many of experiences are echoed in other projects, as the Leskernick project (Wilmore 2007). The problems highlight such issues as the hierarchy of the workplace and the social situations of the excavator. One lesson to take from these projects is the importance of integrating the work procedures that are thought to promote and document reflexivity into normal work so they become a part of the everyday routine.

Another issue connected to the separation of theory from practice is the separation of subject from object. It has been pointed out that the reflexive attempts so far have been rather one sided, prioritizing the subject. Not much attention has been paid to the objects and, in particular, the encounter between the two. The materiality of the objects is rarely taken into account (but see Cooper 2007) as the objects are treated as impassive and passive (Lucas 2001b; Chadwick 2003; Yarrow 2003). This may be described as yet another fault line that has to be dealt with by the methodology.

Future Directions

The future of reflexive approaches within archaeological practice may depend on how the fault lines described above are dealt with. As already noted the post-processual approach to archaeological practice has brought attention to the subjective trait in interpretation. However, it has been pointed out that this line of thought presupposes a distinction between subject and object and that how the subject is constructed through fieldwork is often overlooked in current approaches (Yarrow 2003; see also Hodder 2011: 155).

Further, it has been suggested that this fault line may be overcome by applying a theoretical perspective taken from actor-network theory to

investigations of how archaeological knowledge is created (Yarrow 2003). It entails an understanding of how archaeologists and investigated materials modify one another, in relation to each other, in the act of excavation. Instead of discussing an encounter between subject and object at the moment of discovery, one may say the distinction between a subject and an object is created at this moment. On the one hand, archaeologists create objectivity by embodying archaeological conventions, skills, and knowledge in the process of excavation. On the other hand, the objects create the subjectivity of archaeologists as they are excavated, as their material properties modify the thoughts and actions of the archaeologists. This way the things create the people excavating them as archaeologists (Yarrow 2003).

This line of thought may be used as a base to further explore the notions of materiality and embodiment. These concepts have often been used as means of understanding the past in "material culture studies," phenomenological studies, as well as what is called an "archaeology of the senses." However, these concepts are rarely used to study the present process of interpretation and creation of knowledge in archaeology. There is an unutilized potential in these concepts and areas of study. They could point to a future direction for the development of reflexive approaches in archaeology. The symmetrical relations between persons and things, as they may be described in actor-network theory, may be illustrated in entanglements (Hodder 2011). Again, this has been done describing the past, e.g., at Çatalhöyük (Hodder 2011), not including the archaeologists' material engagement and entanglement during excavation. These areas provide fertile ground for future studies.

Reflexivity in Archaeology

Wilhelm Londoño Díaz
Facultad de Humanidades, Programa Antropología, Universidad del Magdalena, Campus San Pedro Alejandrino, Santa Marta, Colombia

Introduction

Reflexivity is a relatively recent theoretical option in archaeology. It deals with a theoretical position that supposes that archaeological knowledge is determined by both the experience and the context of the investigator. This favors narratives in which archaeological facts are presented through stories that revolve around dialogue, a constant questioning, and diverse possibilities for interpretation. Basically, reflexivity supposes an analysis (a reflection) that the author makes of his own place in the story; it also suggests making explicit the conditions of possibility that determine the object under investigation and the forms for describing it as a scientific object. In this sense, reflexivity deals with a landscape of conditions of possibility that shape the archaeological statement. Viewed from another angle, one reflects upon the statements, which means generating a new enunciation that is equally susceptible to interpretation. This possibility of interpretation on multiple levels is what is known as the "hermeneutic spiral" (Gadamer 2004).

The inclusion of a reflexive agenda in archaeology is relatively recent, and as yet it does not form part of any program, unlike other studies (such as the origin of agriculture or the beginnings of domestication). Singularly, and moreover, reflexivity is repellent to archaeological research agendas based on the neo-evolutionary ideas of anthropology. Such is the case of programs that investigate the energy increment in societies, or the complicating of social differences, or the use of nature as an economic resource; in these cases, reflexivity is something to be avoided, a mere literary distraction. Reflecting on these questions, Joan Gero (1999) found that these processual tendencies unleash

narratives in which society is treated as a machine and people as mere accidents of chance.

Definition

Reflexivity in archaeology is a theoretical field that investigates the conditions of possibility in the archaeologically observed object, namely, the cultural past. The starting point of reflexive archaeology supposes that the research questions, as well as the analytical tools, are situational; a product of the particular historical conditions of the researchers who produce the archaeological discourse. This means that the concept of episteme of Michel Foucault (1999) is very useful to reflexive archaeology; this notion holds that each era shapes the conditions under which a scientific problem is posed, such that the evolution of knowledge becomes the evolution of the methodology of observing objects under investigation. This orientation prevents researchers from wondering about existing disciplinary frontiers or about any prohibitions to the shaping of research objects that question modern ontological divisions.

As a consequence, reflexive archaeology is not interested in knowing how well a certain archaeologist understands a cultural period. It is concerned with knowing why that particular archaeologist focuses on a certain period or cultural phenomenon. Interesting points have arisen from the reflexive archaeology agenda. For example, reflection has shown, in the broadest perspective, that the production of archaeological knowledge gives material support for thinking about social extinctions. Thus, museums are replete with evidence of "disappeared cultures," which the market uses to justify the appropriation of "waste" territories. Many archaeologists have shown how local communities question this rupture and mark it as a tool of domination (e.g., Gnecco and Hernández 2008).

Key Issues/Current Debates

Reflexivity has been both criticized and upheld, according to the different paradigms that have ruled the production of archaeological knowledge. Within these paradigms, two types can be discerned: those that are determined by the premise that there is a reality that can be captured systematically (scientific paradigm) and those that are influenced by the premise that knowledge of reality depends on the interpretive abilities of the individual (hermeneutic paradigm).

Within the scientific paradigm, reflexivity is unwelcome at the disciplinary table. In his book *Analytical Archaeology* (Clarke 1968), David Clarke argued that archaeology has its own analytical universe and that it should develop its own theoretical models, thus generating its own narratives. For Clarke, archaeological narratives should share nothing with historical narratives that are based on the idea of single, non-universal events.

In an early case recorded in South America, the president of Argentina, Bartolomé Mitre (1862–1868), in 1910 asked the archaeologist Adán Quiroga to suppress the poetic tone of his narrative of the cultural material of Northeast Argentina on the grounds that it would obscure the truth of the data being presented. Adán Quiroga responded that his new work would show the suppression of anything literary (Quiroga 2004 [1901]: 13). This point is not without merit, signaling the criticism of reflexivity as associated with specific academic traditions.

Any thought about the situation of the individual producing archaeological knowledge was simply erased by the rise of processual archaeology. In *Archaeology as Anthropology* (Binford 1962), Lewis Binford pronounced that archaeology was devoted to the study of culture, understanding this to be an extrasomatic adaptive mechanism. In Binford's proposed example, the emergence of a certain type of cultural material was evidence of readjustments within society related to the increase of energy. Archaeological explanations should be limited to presenting evidence of economic adjustments, themselves transforming the social and religious spheres of society. From this perspective, archaeological texts should outline systematic changes in culture. Since one is trying to merely recount energy fluctuations, there is no need to pay much attention to the form of the narrative, the metaphors used, or the strategic position of the author behind the data.

Allegations against processualism as a deliberate form of narrating the past came from various quarters and appealed to different interests. From the feminist perspective (Gero and Conkey 1991), for example, researchers began to make anatomies of processual scientific descriptions. It became clear that many narratives were centered on sexist positions (men discussing power, elite property, domination, and hierarchies), including terming "erratic" some interpretations that could have made more sense of the cultural material that was excavated, especially of objects that had belonged to women.

Another militant front against processualism and its narrative impositions came from local communities (Condori 1994). In various sites around the world, voices were raised, making it clear that sites and objects should not be treated as scientific evidence as they actually formed part of the living traditions of many local communities. From this critical area, narratives began to emerge in which archaeologists were in dialogue with the local communities and at the same time reflecting on those narratives (Londoño 2002). The idea that archaeology should only deal with the description of objects exploded under this intense scrutiny: it was fundamental to acknowledge the places where ideas were put forward as well as the local actors affected by the narratives.

Apart from feminist and local archaeologies, criticism of processualism and its lax understanding of archaeological narrative forms also came about with the introduction of theoretical ideas such as hermeneutics, structuralism, and post-structuralism (Tilley 1990). Perhaps the approach most open to reflexivity in archaeology was hermeneutics, as this is based on the idea that reality is meaningful and its interpretation is not determined by methodology as much as by the researcher's competence as an effective interpreter of particular facts. Thus, archaeological research is not a question of finding the correct method but the most adequate metaphors to move the researcher closer to the meanings of the cultural material deployed in the past.

Future Directions

A relation between narrative and reflexivity has been developed in phenomenological approaches in archaeology, assumed to be a contemporary reconstruction of forms of being-in-the-world in the past (Tilley et al. 2007). For phenomenology, it is fundamental to reflect on the place the observer occupies in the space of the investigation. This has obligated archaeological theory to fervently explore theories about the body and the landscape (Tilley 2008).

Phenomenology is not the only area in which reflexivity has risen to prominence. Moving beyond the use of ethnography to generate interpretive models, it has been suggested that ethnography has to bear in archaeological investigations (Edgeworth 2006), not only during fieldwork but also in the generation of meaning, the management of heritage resources, and the hiring of professionals, students, and laborers.

Indeed, a very prolific area that will need reflexivity for its development is the analysis of museums, both as objects and as narratives. More and more, archaeologists work intensely on formulating plans to spread their archaeological knowledge. This will require profound reflection about the manner in which exhibitions are configured, the way in which "noisy" discourses are edited, and the possibilities that other voices will be put forward. Paradoxically, archaeology has not been the place where these reflections have been attempted. Standing out from the crowd, as a forerunner, is the work of James Clifford (1997), especially his work on local museums.

Reflexivity will be important to analyze how archaeological knowledge is positioned as a hegemonic and vertical practice. In this regard, feminist archaeology will play a fundamental role. Narratives with locally situated actors will also be important in generating representations of the past that are not hegemonic, determined by the restrictions of nationalism. This will be, then, an exceptional field for reflexivity as a political and epistemic tool.

Refugees in the Near East and Eastern Mediterranean, Archaeology of

Aaron Burke
Near Eastern Languages and Cultures Department, UCLA, Los Angeles, CA, USA

Introduction

Until relatively recently, remarkably little attention has been paid to the potential for archaeological study of refugees in premodern times, despite related archaeological studies of migration, mobility, nomadism, and colonialism. While identifications of refugees recur throughout archaeological literature in the Near East as a social phenomenon, often through other terms (e.g., squatters, displaced), they are almost never the primary subject of inquiry. This is likely the result of a number of factors. First, to some extent, there exists a general perception that refugees are an exclusively modern phenomenon. Second, refugees are viewed to possess limited agency, and that they are primarily destitute and without means and that they are therefore archaeologically invisible (though this has not diminished a fascination with equally opaque subjects involving migration and mobility). Lastly, assumptions about the distance from which refugees migrate have meant that refugees only seem a reasonable suggestion for a context if their material culture is sufficiently distinct from that of the host culture. Refugees are, therefore, assumed to be a largely ephemeral phenomenon. Nevertheless, a combination of historical documentation and a variety of archaeological contexts, principally in the ancient Near East and eastern Mediterranean, reveal that an archaeology of refugees can be a highly productive avenue for ongoing research, particularly given its pervasiveness as a response to warfare and environmental change wherein entire communities are often forced to relocate. Furthermore, archaeological research of refugees holds

potential for giving voice to marginalized and largely muted historical groups whose experiences were not only significant in their own right but likewise contributed to many more frequently discussed historical and cultural phenomena.

Definition

To begin with, it is necessary to clarify the subject of inquiry for an archaeology of refugees. At the core of such investigations are any individuals or groups, who have been forced from their residences by any of a range of anthropogenic or natural causes (see United Nations 1951). However, such a definition involves preconceived notions of nation states and their borders. More simply and appropriately for archaeological contexts, then, refugees can be identified as "risk induced self-migrants" (Burke 2011). As a result of this, the archaeology that can address these circumstances is, by nature, concerned with understanding circumstances and conditions that informed the experiences of refugees from their places of departure (i.e., home), through potential waypoints along migration routes, and among their destinations. Of particular interest to this line of inquiry is the potential for identifying (1) characteristics of archaeological contexts that signal flight and abandonment of settlements, (2) the factors that may have induced flight, (3) migration routes and conditions, (4) landscapes of refuge, refugee settlement, and factors influencing their selection, and (5) material culture associated with refugees.

Key Issues/Current Debates/Future Directions/Examples

Refugees, as a social category, appear not infrequently among ancient Near Eastern sources, though their identification as such is often elided with, if not obscured by, translations of terms such as "aliens" or "fugitives," or their inclusion among other social groups among textual sources (Burke 2018). Texts from second millennium Mesopotamia and Anatolia, for example, make reference to the return of refugees, who are identified as "fugitives," among the provisions of treaties (see Beckman 1996). Another, particularly clear, case of this occurs in the study of the Hebrew Bible where refugees (Heb. *ger*) are referred to among lengthy discourses on the protection of alien communities, despite an absence of discussions for the contexts of the appearance of these communities or the potential for their identification by archaeological means. In still other cases, well-studied phenomena that may yield hallmarks of refugees have been easily overlooked, with emphasis placed on defining characteristics of migration and the identification of motives behind it (with exceedingly rare explicit identification of them as "refugees"). The vague circumstances behind various migrations invite consideration that these steady and long-term processes may have been the result of persistent stress, whether military, political, demographic, or environmental, and resulted in flight by different communities. The Phoenician expansions from the Eastern Mediterranean during the Iron Age (ca. 1000–800 B.C.), as well as that of the so-called "Sea Peoples" at the end of Late Bronze Age (ca. 1250–1150 B.C.), and Jewish diaspora communities at the end of the Iron Age (post 720 B.C.) are among the better-known case studies, inviting further consideration along these lines. The same may be asked of various historical migrations, including Viking expansion or the seemingly sudden arrivals of other foreign groups during different historical episodes. Likewise, extensive consideration could be given to the refugee-generating processes that were a side-effect of great empires in the Old World.

Several recent case studies from the ancient Near East and Eastern Mediterranean reveal the potential for studying various archaeological phenomena in relation to refugees in ancient contexts. Among the earliest were the inhabitants of agropastoral communities along the arid margins of the Fertile Crescent who, it is suggested, were displaced by the sudden and protracted onset of arid conditions around 4200 years BP that made rain-fed farming unsustainable (Weiss 2014). This contributed to the abandonment of these communities and, evidently, migration to neighboring

regions in which sudden population growth is attested (Weiss 2017), which has been associated with early Amorite groups (Burke 2017). Later in time, during the volatile circumstances at the end of the Late Bronze Age (ca. 1300–1100 B.C.) the displacement of Canaanite and other communities into the southern Levantine highlands, analogous to what occurred among other Eastern Mediterranean communities during this period (Barber 2010), has been identified as social, political, conflict, as well as climate-induced migration. Among the groups later claiming a shared identity in this migration were the Israelites, whose identification with the sudden appearance of small, unfortified hamlets and villages in the highlands of Israel around 1200 B.C. has been often characterized as analogous to refugee phenomena, though not previously explicated as such (Burke 2018), but instead associated these settlements with the sedentarization of pastoral nomads (Finkelstein 1988). An analogous, if largely inferred, set of circumstances have also been associated with flight from the threat posed by an expanding Assyrian Empire in the southern Levant during the Iron Age, principally after the fall of Israel in 720 B.C. (Finkelstein and Na'aman 2004), though not without its critics (Na'aman 2007, 2009). These circumstances, however, can be argued to have contributed to a range of social, linguistic, and artifactual traces in Jerusalem within the state of Judah, which appear to signal the arrival of refugees from its sister state, Israel, just to its north (Burke 2011, 2012). In addition to these are rapid, unplanned expansion of domestic quarters beyond Jerusalem's fortification walls; monumental building programs, such as the expansion of its water system, that were intended to provide for a surge in population; and inscriptions bearing evidence of a northern dialect of Hebrew (Rendsburg and Schniedewind 2010). The archaeological signature of refugees in the Near East is perhaps nowhere more evident than in the cave settlements of Jews during the first and second Jewish Revolts against Rome (Shivti'el 2017).

Studies of more recent historical refugee crises have also sought to employ archaeological methods (Hamilakis 2016). Among these studies, the paramount significance of forensics is clarified by reference to cultural narratives available through ethnographic and historical research. However, these studies rely more on ethnography and forensic anthropology, treating findspots like crime scenes (De León 2013), while employing photography to invoke cultural awareness of concerns surrounding issues like undocumented migration (De León 2015). These studies may, nevertheless, provide insights into the experience of refugees in the course of migration, which pertain to premodern archaeological contexts, though its value as such remains to be demonstrated through the correlation of ancient sites with modern ones; migrant stations have not been identified in antiquity, for example.

Despite its evident potential, a number of challenges limit opportunities for the archaeological study of refugees in premodern contexts. Foremost is the identification of the groups in question since the label refugee is a social and political one, and, if such a category was significant to such groups, it existed concurrently with identities held by these individuals prior to their flight. In the absence of written sources, in both modern and ancient contexts, it can be difficult if not impossible to be certain that a particular context is to be identified with refugees per se. In this regard, anthropological and NGO literature has been employed to articulate an approach to exploring refugee resettlement, the most concrete archaeological aspect of the refugee experience in antiquity. Of note is the impoverishment risks and reconstruction (IRR) model articulated by Michael Cernea, who employed anthropological approaches to the study of refugees over the past several decades, albeit in an effort to identify strategies for the successful resettlement of refugees (Cernea 2000). Building upon decades of anthropological research of the resettlement plights of refugees, it identifies universal risks experienced by refugees during resettlement (which, in its original context, was intended to permit addressing these through relief efforts). These risks include landlessness, joblessness, homelessness, marginalization, food insecurity, increased morbidity and mortality, loss of access to common property assets, and community

disarticulation. To this, of course, are added general security concerns that accompany refugees from the moment that their flight begins. All of these characteristics are commonly addressed even in recent ethnographic and archaeological studies of modern refugees, as discussed above.

The phenomena associated with refugees identified by the IRR model can be correlated with individual lines of archaeological evidence, that when taken together with other evidence, such as historical sources, the model has been employed to facilitate the identification of refugees in archaeological contexts (Burke 2011). Landlessness, for example, is identified through the abandonment of sites or landscapes, rapid site and settlement growth in neighboring territories, and in settlement pattern shifts, in particular accompanying abnormally rapid growth rates for settlement within a region or among particular groups of settlements. Joblessness, especially varying forms of nonagricultural subsistence, is likely to be reflected not in the absence of employment, which leaves no direct archaeological trace, but rather may be identified in the efforts made by polities to provide employment and for the essential needs of newly arrived refugees on relatively short notice. Military conscription and mass labor projects are, for example, among the principal and relatively conspicuous avenues for the potential employment of refugees, and one of the principal reasons that, for example, vassal treaties in the ancient Near East often stipulated the repatriation of refugees, often labeled fugitives in modern translations. Homelessness, while an admittedly modern terminology, might be reflected in the sudden growth of particular settlements, often extramurally at first, in whole quarters within settlements, or the identification of squatting within the remains of buildings. By contrast with modern housing projects, most households in antiquity were built and maintained by their inhabitants and therefore they are only distinct from other domestic structures insofar as the architectural traditions and domestic assemblages of the newcomers are themselves sufficiently distinct (i.e., foreign) in appearance. However, much of the evidence for premodern conditions suggests that most refugee migrations were relatively short-distance phenomena (i.e., to the nearest safe region, often relying upon extant social networks). Thus, the sudden increase in domestic buildings at a site, often resulting in a substantial increase in the size of a settlement, may account for efforts to mitigate the homelessness facing these newcomers. Likewise, the material culture is often unlikely to yield a starkly different assemblage.

Marginalization, though more difficult to identify archaeologically, may be embodied in the isolation of refugee communities to the periphery of settlements or within particular quarters within a settlement or, similarly, within settlements in remote locations including caves. Occasionally, marginalization may be more readily detected in written sources such as inscriptions, which are themselves often archaeological artifacts. Food insecurity, one of the more conspicuous refugee concerns, is likely to be reflected by the adoption of a wide range of subsistence strategies that expose the inconsistency and unpredictability of food sources for refugee communities, whether through the extensification – into new regions – or the intensification of agricultural production. The identification of these strategies requires, however, a high degree of resolution and chronological control from archaeological excavations, and many earlier excavations simply do not yield such data. Additionally, when skeletal evidence is available, there may be evidence of malnutrition, that may have resulted in increased morbidity and mortality, likely associated with various types of stresses upon refugee communities, such as food insecurity. The appearance of new cemeteries in areas previously unused at a period contemporaneous with the expansion of a settlement may corroborate the presence of refugees as well. As refugee studies indicate, given the varied economic level of refugee communities, it is impossible to predict the affluence of burials within such cemeteries, or that of refugee settlements as a whole, and for this reason, poverty is not necessarily a correlate to the identification of refugees. Furthermore, as with food insecurity, a certain quality of data collection is necessary to permit this type of assessment. Perhaps one of the more challenging of the risks to consider is the loss of

access to common property assets. However, assets such as commonly accessed resources such as ritual and cultic sites (e.g., temples and shrines) and burial grounds would likely need to be replaced for refugees, where changes in practice were not adopted almost immediately to satisfy such losses. If unresolved, access to required resources could lead to increased social conflict. Community or social disarticulation may be manifest not only in a breakdown in kinship bonds but also a loss of social capital, which can contribute to economic loss as well as social alienation. Albeit among the most challenging of the risks to identify archaeologically, indicators of kinship relationships and markers of social integration may permit a diachronic investigation of the social disarticulation of households and kin groups. Changing burial traditions, cultural adaptations, and other changes may signal not only this disarticulation as negative but, conversely, positive and productive interactions with host communities that result in the formation of new social groups through intermarriage, adoption, etc.

More general security concerns, which usually simply assumed in modern studies of refugee scenarios (and for this reason was not articulated among the IRR's resettlement concerns), also manifest themselves in the archaeological record of refugee communities. These are often reflected in dispersed settlement patterns and settlement within marginal or remote locations (e.g., landscapes of refuge). However, they may also be manifest in the creation of fortified complexes, as in the Cyclades at the end of the Late Bronze Age (Barber 2010). Hoarding, if not more appropriately identified as hiding practices, reveal another manifestation of security concerns. Food insecurity can therefore also be a part of this, wherein practices of burying caches of food in pits or small silos reveal a change in earlier strategies, as for example, during the early Iron Age in the southern Levant.

While the IRR model offers one approach to systematic consideration of archaeological contexts with reference to refugees, the body of anthropological literature concerned with the study of refugees is vast. Consequently, ample room exists for the exploration of other avenues for the identification of refugee-related phenomena. The aforementioned model does not, for example, explicitly address the concerns of internally displaced persons (IDPs) that have become a significant component of modern refugee studies. While at first glance such a concept may not appear to be relevant to pre-modern contexts, the frequent identification of postdestruction occupation with squatters by archaeologists may offer one of the most salient contexts for greater exploration of the issues surrounding IDPs that are relevant to archaeological investigations. Consequently, as sensitive as the subject is within modern studies, archaeologists may greatly benefit from the consideration of ethnographic and cultural studies of the plight of refugees since the early twentieth century.

Regional/Site Museums

Susan R. Frankenberg
Museum Studies Program, Department of Anthropology, University of Illinois, Urbana, IL, USA

Introduction

The term "site museum" was first used in the 1950s to describe a museum at a place of scientific or historical significance whose purpose was to interpret the site to visitors (Lewis 1959). Site museum at that time referred both to museums at historic and archaeological sites and to visitor interpretive centers at natural and historic monuments and within scenic parks. Shortly thereafter in the 1960s, the term "regional museum" began being used to identify local and specialized museums that interpreted objects and phenomena from a specific geographical location such as a district, landscape, or village. Like site museums, regional museums encompassed both natural and cultural history and were based in disciplines in addition to archaeology. Subsequently, outside the discipline of archaeology, "site museum" became an overlapping term for outdoor and open-air museums including historic houses, living history museums, folk museums, heritage villages, and historic parks (Shafernich 1993; Moolman 1996; Swanson 2009). And while the original use of "regional museum" suggested multiple sites or locales within a

defined area, the term was sometimes applied to individual site museums, community museums, and ecomuseums.

Expansion of these terms occurred in parallel with broadened definitions of heritage and culturally significant places within international policy (see Ahmad 2006; Cleere 2010). Unfortunately, such expansion has also led to confusion. "Site museum" has erroneously been applied to museums with buildings dislocated from their original sites and reconstructed in configurations that did not exist in the past. "Regional museum" is now used in several countries to designate district museums within a hierarchical museum system organized and overseen by a national-level ministry of culture or heritage trust. Both site museums and regional museums are associated with defined geographical locations and are tasked with interpreting aspects of the culture, history, and/or environment of those locations to visitors. Importantly, site and regional museums often attempt to communicate a sense of place (sensu Davis 2011) that enables visitors to understand the significance of a locale and to feel connected to the past. Archaeological site and regional museums fit within this broad definition but possess unique characteristics and face challenges based on the nature of archaeological sites, archaeological data, and perceived relationships with living communities.

Definition

Despite the large amount of work devoted to creating archaeological museums and promoting public outreach and heritage tourism through them (see, e.g., Stone and Planel 1999; Grabow et al. 2007; King 2011; Okamura and Matsuda 2011; Skeates 2017), there are few published definitions of archaeological site and regional museums. A notable exception is Silverman (2006: 4), who defines an archaeological site museum as a building at an archaeological site which displays materials excavated from that site and perhaps related sites together with explanatory texts that interpret the site and its archaeological culture for the public. Erturk (2006) and Swanson (2009) similarly identify an archaeological site museum as an archaeological site with associated interpretive elements such as text panels or an on-site museum and require that the site be preserved, protected, and periodically open to the public. Paardekooper (2012, 2014) includes some archaeological site museums in his review of archaeological open-air museums, but such open-air museums may not be located on the sites themselves and often do not exhibit archaeological artifacts. All of these definitions stress the integration of interpretation for the public with the archaeological site itself, but only Silverman's definition also requires exhibition of artifacts or other archaeological materials. Additionally, neither definition differentiates site museums from regional museums.

Expanding on this and in line with general definitions of museums, an archaeological site museum collects, preserves, researches, exhibits, and communicates evidence and interpretations of the human activities that occurred at that site to the public. By extension, an archaeological regional museum collects, preserves, researches, exhibits, and communicates evidence and interpretations of past human activities that occurred across a number of sites or landscapes to the public. In both cases, this communication should explain the site's or region's significance or relevance and frame the evidence and interpretations with respect to archaeological research methods and various historic, environmental, and other contexts. The goal of archaeological regional and site museums is to translate the archaeological record, or evidence of the past in a specific locale or region, for public understanding and consumption. Translation or interpretation requires more than simply displaying or documenting the material record; it requires encouraging visitors to ask questions of the material record and about its meaning (Chan 2011).

Key Issues/Current Debates/Future Directions/Examples

The issues and debates faced by archaeological site and regional museums, and by the

archaeologists working with them, involve balancing museological, archaeological, and heritage management theory and practice priorities (see, e.g., Watson 2007; Graham and Howard 2008; Okamura and Matsuda 2011), oftentimes in the face of contradictory market pressures and transnational policies. Challenges stem from the competing needs of the sites, their visitors, their researchers/caretakers, and the communities within which sites are located both geographically and genealogically. Additional challenges arise from differences among scholars, administrators, and policy-makers over the primary purposes of these museums and the best ways to achieve those purposes. Site museums are seen as a way to enable archaeologists to achieve their ethical responsibilities with respect to public engagement (Silverman 2006), but these museums become a double-edged sword when stakeholders disagree over how, and what, aspects of a site are to be preserved and interpreted, and for whom. Debates center on regional and site museums as stewards, as interpreters, as heritage, and as instruments in cultural policy, tourism, and development.

Archaeological site and regional museums collect, preserve, and exhibit materials and data from one or more archaeological sites and often have roles in the continued preservation and management of those sites. As simultaneous stewards and presenters of the archaeological record, these museums must balance preservation in place with excavation and reconstruction and the use of original items with restorations and reproductions. Attempts to achieve this balance lead to both specific debates over reconstructive techniques and broader controversies over preservation philosophies. A conservation ethos with respect to archaeological sites and artifacts can put museums at odds with tourism and development demands while also serving as a rallying ground for preservation legislation and activism at the local, national, and international levels. Numerous examples of both cases over the past decade are documented in the journals *Conservation and Management of Archaeological Sites* and *Archaeologies: Journal of the World Archaeological Congress*.

Conservation and preservation issues also play into the technologies chosen for interpretation and the relation of the museum to knowledge production. Contemporary regional and site museums, to the extent that they participate in now globalized professional museological discourse (Muller 2005; Skeates 2017), approach interpretation as explanation aimed at provoking or enabling visitors to create their own knowledge and make their own meaning about the site(s) and archaeology. This presents several challenges with respect both to the basis of interpretation and to how visitors are conceptualized and addressed. Because of the overwhelming amount and complexity of information yielded by archaeological sites, interpretive planning within regional and site museums is a highly selective process in which only a limited number of archaeological times, features, spaces, and stories are exhibited and communicated. Decisions about which stories to convey, and from what perspectives they should be told, require a clear understanding of visitor diversity, needs, and capabilities and control over the current state and future potential of archaeological and museological research.

Archaeological site and regional museums act as both interpreters and places of heritage, and because of the power relationships involved in knowledge production, these museums can be caught up in what has been referred to as the politics and poetics of representation (see Bell 2012). The information and interpretation presented by site and regional museums can be read in different ways and put to different purposes by visitors and critics. These museums portray and explain relationships between ideas and things and persons in ways that can promote collaborative generation of knowledge and support identity formation and expression within particular groups. Conversely, these same actions may provoke contestation and disputes among groups with competing claims on the museum. The role of regional and site museums in the production of identity and heritage is highly variable and involves related issues of authenticity, cultural commodification, and authority. Site and regional museums are also subject to public and scholarly

debates over agency and control in the realms of cultural policy, tourism, and development.

In many countries, archaeological site and regional museums are seen simultaneously as part of cultural tourism networks or destinations and as a way to implement government-based heritage management initiatives or cultural policies (Erturk 2006; Demoule 2012). They are seen as new industries in economically disadvantaged areas, as reasons for international development expertise and economic support, and as solutions to strained relations with ethnic minority or other excluded population sectors. These increased expectations and broader roles impact the kinds of interpretation, preservation and conservation practices, and physical configuration possible at regional and site museums. To meet the demands of tourism, regional and site museums must provide interpretation at different levels to accommodate the diverse expectations, interests, and capabilities of an expanded visitor base and may view visitors from a consumer or marketing perspective. These museums may also uncritically alter their missions and programming or adopt various globalizing standards to accommodate policy initiatives or to qualify for international support.

Interestingly, a number of digital applications originally developed to encourage or accommodate cultural tourism at archaeological museums, including site museums, are increasingly being used to promote heritage learning among domestic visitors and local communities. These applications range from social media that primarily serve a marketing function (De Man 2015) to interactive storytelling (Deliyiannis and Papaioannou 2014), serious gaming (Mortara et al. 2014), and collaborative research (Bonacchi et al. 2014) designed with learning in mind. Several of the applications use augmented reality and games on handheld mobile devices to assist visitors in interpreting an archaeological site as they move around it (see, e.g., Angelopoulou et al. 2011; Etxeberria et al. 2012). This new trend in digital heritage interpretation at archaeological sites and site museums suggests a renewed interest in promoting learning and a more democratic museum experience, but the impact of these applications on visitor experiences has yet to be fully assessed. Evaluation at the present time still lies in the realm of visitor satisfaction surveys and user testing, rather than learning outcomes. The issues and debates faced by archaeological site and regional museums are not restricted to particular regions of the earth, and how site museums address these challenges is shaping the future directions and configurations that they will take. What is currently variable across the world is the specific content, emphases, daily operations, and appearance of individual museums. Some regional and site museums address the nature of archaeological investigation or introduce multiple perspectives within their interpretations, while others do not. Some extend reconstruction beyond simple architecture to demonstrate various past behaviors through performances and reenactments. The variability among contemporary regional and site museums is due in part to the incredible diversity of human history, variation inherent in the archaeological record, and local and state level differences in archaeological and museological practice. With the adoption or imposition of international standards, some of this variation may disappear but challenges facing archaeological site and regional museums will not.

Register of Professional Archaeologists (RPA)

Patrick H. Garrow
RPA, Cultural Resource Analysts, Inc, Knoxville, TN, USA

Basic Information

The Register of Professional Archaeologists (RPA) was formed in April, 1998, and succeeded the Society of Professional Archaeologists (SOPA), which had been formed in 1976. SOPA was self-defined as a professional society, and offered basic certifications in field and laboratory research, with additional certifications in areas

such as cultural resource management, teaching, museology, and underwater archaeology. Applicants agreed to adhere to a code of ethics that included a "Code of Ethics and Standards for Research Performance," which applied to individuals, and institutional standards that applied to the program within which the member conducted his or her research. SOPA also had defined standards for field schools (Jameson 2004: 38).

RPA was established as a result of the efforts of a joint task force composed of representatives from SOPA, the Society for American Archaeology (SAA), the Society for Historical Archaeology (SHA), and the Archaeological Institute of America (AIA). The SAA, SHA, and AIA became sponsors or RPA when it was formed, and were later joined in the same role by the American Anthropological Association. The governing Board of RPA consists of representatives of those four sponsors, while the officers, which include the RPA President, President-Elect, and Secretary-Treasurer, are elected by RPA registrants (Beaudry 2009: 17; www.rpanet.org).

RPA streamlined the registration process and dropped the specialty certifications that had been offered by SOPA. Two types of applications are offered. The Short Form application is offered for an applicant who:

- Holds an advanced degree with a specialization in archaeology
- Has designed and executed an archaeological study that has been reported in the form of a Master's thesis or Doctoral dissertation
- Accepts the responsibilities and standards described in the Code of Conduct, Standards of Research Performance, and Grievance Procedures of the Register of Professional Archaeologists (www.rpanet.org)

The Long Form application is required for those who have an advanced degree, but lack the specialization in archaeology and/or a thesis or dissertation that dealt with a substantive archaeological issue. Both Long and Short forms are reviewed and accepted or rejected by the RPA Registrar, who is elected by vote of the membership (www.rpanet.org).

The RPA "Code of Conduct" and the "Standards of Research Performance" replaced the SOPA "Code of Ethics and Standards for Research Performance." The Code of Conduct states:

> Archaeology is a profession, and the privilege of professional practice requires professional morality and professional responsibility, as well as professional competence, on the part of the practitioner (www.rpanet.org).

The Code of Conduct spells out what archaeologists shall and shall not do when dealing with the public, dealing with colleagues, employees, and students, and dealing with employers and clients. That code incorporates some elements of the SOPA institutional and field school standards, and provides clear ethical guidance to registrants (www.rpanet.org).

The Standards of Research Performance spell out standards that registrants must meet when engaging in any type of archaeological research. In broad terms, the standards require that the registrant "prepare adequately" for the research project, follow the prepared "scientific plan of approach" to the extent possible; ensure that adequate records are kept to ensure that provenience information is preserved in the laboratory; curate the project materials with an appropriate curatorial facility "unless otherwise required by law"; and disseminate the research results to "appropriate constituencies with reasonable dispatch" (www.rpanet.org).

The Code of Conduct and Standards of Research Performance (The Code) are enforced by RPA through a written grievance procedure by an elected Grievance Coordinator. Once a complaint is received, it is within the discretion of the Grievance Coordinator to dismiss the complaint or to appoint a Grievance Committee composed of two RPAs to work with the Grievance Coordinator to investigate it. The Grievance Committee prepares a report at the conclusion of its investigations that can recommend that the case be closed for lack of supporting evidence, that the person investigated be allowed to accept admonishment or censure with no further action, or that the case be referred to the Standards Board, the membership of which is elected by the RPA

registrants. The Standards Board then schedules a hearing to hear the case and takes testimony from all those who are involved. The Standards Board is required to render its opinion within no more than 30 days after the hearing. The Standards Board issues a "finding of fact" which includes a determination if any of the allegations are true and imposes disciplinary action if one or more allegations were supported. The actions taken may range from an admonishment to termination of registration (www.rpanet.org).

Major Impact

The major impact of RPA is that the number of registrants has increased from less than 1,000 members under SOPA to well over 2,000 at present. This increase is highly significant because it brings many more archaeologists under the provisions of the RPA Code. The RPA process is viewed by those in other disciplines as a certification process for professional archaeologists that is similar to other professional certifications. This has particular value to archaeologists involved in cultural resource management. RPA now certifies archaeological field schools that are conducted under the guidance of an RPA following a responsible research plan, and offers field school scholarships. RPA has recently begun certifying continuing education programs, which should be a significant benefit for its members. A founding principle of RPA was to "advance professionalism in archaeology," and that goal is certainly being met.

Reichel-Dolmatoff, Gerardo

Wilhelm Londoño Díaz
Facultad de Humanidades, Programa Antropología, Universidad del Magdalena, Campus San Pedro Alejandrino, Santa Marta, Colombia

State of Knowledge and Current Discussions

Gerardo Reichel-Dolmatoff's work is important for South America's archaeology and anthropology; he together with his wife Alicia Dussán began to offer, with other scholars, the first disciplinary data that would mark the course of Colombian archaeology and anthropology. Reichel-Dolmatoff's work has been discussed by different scholars (Laurière 2010) who have pointed out the iconic phases of what could be considered the history of his academic production. It is necessary to mention something about this and given the fact that this anthropologist was the first to produce a series of data on the archaeology of Colombia, to some extent his history as a scholar coincides with certain aspects of the history of the anthropology in the country.

It is agreed that Reichel-Dolmattoff's arrival took place at the end of the 1930s when the liberal party ruled Colombia. They, unlike the conservative party, promulgated a certain integration policy of rural communities into the nation project. In this context, the emergence of social sciences in

the country was possible. This tendency strongly opposed the eugenics projects that were encouraged by certain fascist-driven currents in Colombia. It should be remembered that Colombia, like other the countries of the southern cone, tried at the beginning of the twentieth century to exterminate the indigenous population and promote the migration of Europeans from Western Europe, but certain liberal ideologues restrained the initiative and proposed an integration strategy that was based on the idea that, through education, assigned to the Catholic Church, the indigenous would become citizens of the republic; this initiative was known as the "reduction of savages" (Londoño 2003).

With the consolidation of the liberal republic, the State began to treat the issues of the nation's diversity with some scientific rigor, distancing itself from the models of extermination of the native population that had marked the processes of consolidation of the State in the southern cone in the last decades of the nineteenth century. This turn in national politics, in relation to indigenous communities, allowed the establishment of some ethnology institutes that were the predecessors of the three oldest anthropology departments of Colombia (Pineda1984).

The liberal republic of the 1940s (Silva 2006) called for a certain cultural recognition of the country; the premise was that there could be no nation unless the territory was known in some way. Likewise, the international conventions signed by Colombia to protect the indigenous population made it necessary to establish a national ethnic information system that prevented, as agreed, the indigenous people's extermination in exchange for their integration as citizens (Pineda 1984). It was in this way that Paul Rivet, fleeing from the Nazi's advance into France, was able to found the National Ethnological Institute in 1941. There is enough evidence to show that by 1941 Reichel-Dolmatoff was close to Rivet, up to the point that Reichel, without no institutional affiliation or role as an ethnographer, had the possibility of accompanying him in the National Ethnological Institute official explorations (Laurière 2010, 114). The Ethnological Institute foundation takes place in 1941, but Reichel-Dolmatoff had arrived in the country in 1939 and was recognized in the cultural scene of the capital as a painter, because, as a matter of fact, he had presented paintings in the newly founded art galleries of Bogotá. While there are different sources about the details of Reichel's arrival in the country, it is clear that his entry was favored by the series of laws that had made Colombia a possible destination for people with German passports and Caucasian appearance. Following a policy that could be labelled as a fascist, the Colombian government, on the eve of the Second World War, had banned Jews from Europe from entering the country (Galvis and Donadío 1986, 217). Given the Austrian origins that were recognized to Reichel, his arrival in 1939 to Colombia was easy.

In 1943, Gerardo Reichel-Dolmatoff marries the anthropologist Alicia Dussán, and thus the couple begins a project of exploration of the country. In the light of the present time, in Reichel-Dolmatoff's work, some inflections defined by his concerns could be discerned at particular moments of time. A first inflection would be his early studies on the archaeology of northern Colombia where, through archaeological surveys and colonial sources' consultation, he achieves two major disciplinary contributions. The first would be a documentation of archaeological sites in the coastal and mountainous areas, and the second the generation of some periodizations about the region that was based on elements of the archaeological record such as ceramic decorations (Reichel-Dolmatoff 1954). The other inflection is the contributions to a certain ethnography of an environmentalist nature, where he pointed out that the natives were ecologically friendly given their animistic cultures. These arguments are developed throughout the 1960s and 1970s. It is in the latter decade that Reichel begins to be recognized worldwide as an expert in Amazonian lowland societies regarding the use of hallucinogens. This fame, no doubt, was due to his membership in the Department of Anthropology at the University of California, Los Angeles; even Reichel managed to sign publications pointing to this

university as the institution to which he was affiliated (Reichel-Dolmatoff 1985a). Finally, in the 1980s and 1990s, there is another period, where it is possible to appreciate the appearance of synthesis of the country (Reichel-Dolmatoff 1997) and studies on the belief systems of Amazonian societies (Pineda 2003).

Something to be mentioned here is the fact that Reichel, while he was interested in the archaeological record of the North of Colombia, and while trying to offer regional syntheses of historical sequences through some archaeological features, helped to build the myth that some ethnographic tribes were the descendants of pre-Hispanic cultures whose remains began to be studied by archaeology. This is clearly seen in the idea of a continuity between the Tairona tribe, described by chroniclers as the one with the greatest resistance to the conquest, and the Kággaba or Kogui which, according to Reichel, was one of the best preserved tribes in northern Colombia (Reichel-Dolmatoff 1985b, 16).

This idea about the aforementioned Tairona-Kogui continuity was generated in the late nineteenth and early twentieth century, by American archaeologists, e.g., Marshall H. Saville, who had studied the Spanish chronicles with judgment. According to the information provided by Gregory Mason, a PhD student from Saville, he suggested excavating in Colombia to find Taironas remains (Mason 1938, ix). Saville knew about the Tairona collections, because at the beginning of the twentieth century some anthropologists who had been in Santa Marta had taken samples of pottery and gold to the United States (Giraldo 2010, 46). These first collections had been the result of some philanthropists' funding who had obtained their fortune from oil as George Gustav Heye, founder of the Museum of American Indian in 1916.

Today with the declassified archives of the First World War, it is known that Heye, through his foundations, financed archaeologists to conduct research in South America while acting as double agents of the emerging intelligence agencies of the United States. This was the case of Samuel K. Lothrop, who gathered, financed by Heye's resources, large collections in Central America and South America.

In the United States, at the beginning of the twentieth century, the idea of a probable continuity among the tribes described in the chronicles and current populations promised much for the development of pre-Hispanic society's archaeology. As it can be seen in the research that was taking place in the United States in the 1920s, these scholars knew the books written by chroniclers and priests about the North of Colombia very well. This was possible, undoubtedly, because of the archival investigations that were carried out in Spain, as well as the publication of works written in the sixteenth, seventeenth, and eighteenth centuries, which were published in Madrid and Paris in the nineteenth century and that circulated in America. In these works, repeatedly, it was pointed out that the conquerors had defeated the fierce Tairona, in the epic battles of the sixteenth century.

As early as 1953, Reichel-Dolmatoff, based on his ethnographic research, had determined that the Kággaba or Koguis, an ethnic group from the Sierra Nevada de Santa Marta, in northern Colombia, discriminated the Tairona in their genealogies, recognizing them as a different tribe (Reichel-Dolmatoff 1953, 29). Yet, Reichel did not maintain this position and used the name, as the conquerors had done, to refer to the tribes with whom they had fought in the conquest processes of the present North of Colombia. In the works where Reichel had the opportunity to present large-scale temporal and spatial visions of northern Colombia, he used the Tairona notion to refer to a nation that was neither a State nor a mere tribe, which inhabited the Sierra Nevada de Santa Marta until their submission in the sixteenth century. In the words of Reichel, the Muisca and the Tairona were the only two manifestations of social complexity of Colombia's archaeology; these two societies:

> Achieved a somewhat wider political cohesion. One can hardly speak here of 'incipient states', much less of 'kingdoms' or 'empires'; rather, they were strong villages federations in which a large numbers of settlements and peoples of the same ethnic stock were united under the control of a single individual. . . (Reichel-Dolmatoff 1965, 142)

As it can be seen, Reichel resumed the American tradition of thinking about the archaeological record of the North of Colombia, as evidence of the existence of the fierce tribes mentioned in the chronicles. By the eighteenth century, the historiographical imaginary pointed out that the conquests of the past two centuries had confronted the conquerors with the Tairona, which in some stories were compared with the antediluvian beings mentioned in the Genesis of modern bibles (Julian 1854). As reviewed by a variety of authors, America was already invented before being described (O'Gorman 2010).

According to this scenario, with the institutionalization of anthropology in Colombia in the 1940s, and with the emphasis that Reichel-Dolmatoff put on investigating the Kággaba tribes and Tairona archaeological sites, many of his students, who did research in the Sierra Nevada from Santa Marta in the 1970s and 1980s, openly pointed out that the Kággaba were the main descendants of the Tairona who, as a result of what was happening in the 1970s with the aperture toward environmentalism, were clear evidence of sustainable management and ancestral ecosystem. These ideas were legitimized by the project of investigating these tribes, to replicate their ecosystem management in the peasant societies that began to occupy the mountains of the Sierra and that were seen as predators (Serje 2008). Consequently, the Tairona-Kogui continuity was declared in the 1970s, appealing to the tradition instituted by Reichel-Dolmatoff, which in turn had been the result of retaking these presuppositions of American archaeologists such as Gregory Mason, who in turn had taken them back from Saville. However, since the chronicles indicated that the Tairona were warriors, and given the passivity of the Kággaba, Mason in the 1930s pointed out that, probably, the descendants of the Tairona were not the Kággaba but the "Goajiros" (Mason 1938, ix).

When reviewing Reichel's work, it has also to be added that other authors have offered images that auscultate his previous life before arriving in Colombia. According to this documentation (Oyuela-Caycedo 2012), he was an active supporter of the Hitler militias, and, just before his migration, he was a recognized murderer of the National Socialist paramilitary groups. This is not a minor detail, since, in fact, the peculiarities of Reichel's life are insipid when making a historiographical analysis of his work and its relationship with the development of anthropology and archaeology in Colombia. Some authors point out that when Reichel was questioned about his family background, he explained that he had been educated at a Benedict school in Munich and that he also received great influence from his family environment where works of art and history books proliferated (Lomnitz 2017). In this regard, some people have documented how Reichel-Dolmatoff was expelled from school, so his idyllic training history is a lie (Oyuela-Caycedo 2012). At the age of 14, Reichel was expelled from the Benedict College for promoting pro-Nazi organizations, so his time at school was brief. With a disintegrated nuclear family, since his father abandoned them, and with problems at school, Reichel's adolescence was spent in his eagerness to ascend in the fascist militias. Apparently when Reichel crosses his second decade of life, he has serious problems inside the party, so he leaves Germany and takes refuge in Paris at the beginning of the 1930s. It is in this context where he knows about the possibilities of migrating to Colombia, where he later on becomes part of the ethnological missions that would be in charge of the French ethnologist Paul Rivet.

If, as biographers point out, Reichel was born in 1912, by 1943, at the age of 31, he was already making his first publications in Colombia on archaeology of the center of the country. Something important in this decade has to do with the reports made by Reichel and Dussán about the activities of the Magdalena Ethnological Institute in 1947 (Reichel-Dolmatoff 1947). As it can be seen in these publications, the couple had been given the task of doing some research, and publications on behalf of the aforementioned institute, which complemented, in the North of Colombia, the ethnological works that were already being carried out in other parts of the country with the Ethnological Institute of Cauca (1947), the

Ethnology Service of Antioquia (1945), and the Institute of Ethnological Research of the Universidad del Atlántico (1947).

When observing the reports of these decades and the concerns they cover, the routine procedures appear as descriptions of archaeological materials or specific components such as generalities of indigenous economies. Certainly, in his activities at the Magdalena Ethnological Institute, Reichel sowed some disciplinary concerns such as the evaluation of the information available in the colonial documentation on the indigenous communities of northern Colombia, which led him to make some inventories of colonial documents that were useful for the understanding of the pre-Hispanic past. He was also worried about the archaeological sequences, so he proposed his first systematizations in the 1950s (Reichel-Dolmatoff 1954).

Reichel-Dolmatoff played a very important role by being one of the first to found institutes of anthropological studies in a region that, like Magdalena, was characterized by the presence of abundant indigenous communities and by the existence of huge vaguely studied archaeological sites. This is how a large number of archaeological materials emerged that served to define the ceramic typologies of northern Colombia. Something that should be mentioned is that these typologies are generally intuitive and confusing, while archaeological complexes in many cases were considered ethnic groups (Reichel-Dolmatoff, Colombia 1965), and also the type definitions were made without delineating the series of attributes that defined the types.

At the beginning of the 1950s, Reichel published a book where he summarized the information available in the General Archive of the Nation about the tribes of the old Spanish province of Santa Marta (Reichel-Dolmatoff 1951). In that book, it was possible to see how Reichel used the ethnohistoric information available to map the probable distribution of the tribes and the formation of provinces at the arrival of the conquerors. Likewise, he proposed a periodization of the archaeology of northern Colombia in which he would place some initial stages that could be equivalent to the Paleolithic, which would lead to phases of formation (American formative) that would eventually consolidate into developments of social complexity. With some variations, this periodization accompanied Reichel throughout his life and was ratified in his archaeology texts from Colombia (Reichel-Dolmatoff 1997).

In the 1950s Reichel had a prolific activity, especially in his records of sites close to the swamp system that make up the corridor between the mouth of the Magdalena River in Barranquilla and the city of Cartagena. Most of these sites were catalogued by Reichel as formative given the presence of shells and ceramics, associated with artifacts to process cassava. In general, these sites were characterized by little evidence of sedentary life, but with differentiating features such as the use of ceramics, which allowed us to think of semi-nomadism.

The formative was defined, consequently, as the period where the dependence on the collection of molluscs, added to the recollection of roots, allowed the basis for village life that was the distinctive feature of the regional development period. This idea is very important because Reichel always thought that there was a need for a mechanism to strengthen the villagers' ways of life that he considered, in any case, as post-formative. From Reichel's appreciation, what would be popularized was the idea that the formations of the littoral zone presented forms of adaptation of the formative that were earlier than the manifestations of the sierra characterized by their system of villages and roads, both marks of complexity development processes. As Lanhebaek properly pointed out, this apparent distribution of temporalities is not a feature of the pre-Hispanic past but the result of archaeologists' emphasis on studying "lost cities" without paying attention to coastal sites.

Undoubtedly, this is one of Reichel's most popular ideas, and, in turn, it is one of the best kept arguments of his disciplinary heritage. Yet, it has been shown that his thesis does not have empirical support since there is no systematic process of absolute dating that allows us to infer, in the case of northern Colombia, the population patterns of the sierra regions versus the

guidelines of population of the coastal regions, indicating that the former are more recent than the latter.

As some scholars of Reichel's work (Uribe 2017) have pointed out, before the question of his fascist past came up, panegyrics abounded about his work, especially signalling two things: first, the recognition of religious rituals of complex belief systems in the indigenous communities' use of certain hallucinogens. In a country as traditional as Colombia, talking about the fact that indigenous rituals had an anthropological sense was a challenge and a great contribution to the humanities. Second, the other contribution was having tried a global vision of the country's pre-Hispanic past, through his synthesis and descriptions of sites. No one knew Colombia better than Reichel-Dolmatoff and his wife Alicia Dussán, because they had the opportunity to visit indigenous communities that still did not face the rapid processes of change that occurred in the last quarter of the twentieth century.

Reichel-Dolmatoff's idea regarding the anthropological dimensions of the consumption of sacred plants probably came from his collaboration in the book edited by Johannes Wilbert on horticulture in indigenous communities in South America (Wilbert 1961). Wilbert was an active collaborator of the La Salle Foundation in Caracas, which through its famous "Anthropological" magazine spread important ethnographic and archaeological studies of the native communities of Venezuela. As it can be seen in the magazine's publications, Wilbert's entries disappear in 1964, when he is appointed director of the Latin American Centre at UCLA. In that book, Reichel would publish an article that would later on have great influence, entitled "The Agricultural Basis of the Sub-Andean Chiefdoms" (Reichel-Dolmatoff 1961). Basically, Reichel's thesis in this book was that corn constituted the device that had allowed the passage from the formative to the regional development. When you review the article, the descriptions of the processes are very general, and there are not really paleobotanic studies that support the claims; it is a purely speculative document that was not built with the intention of being a model to evaluate.

In that same decade, Reichel would arrange with Glyn Daniel, who was an archaeology professor at Cambridge University, an issue on Colombia, for the series he directed for the Thames and Hudson Publishing House, founded by the couple Walter and Eva Neurath, remembered for their anti-Nazi activism in the 1930s in Germany. In the first edition of this book (Reichel-Dolmatoff 1965), which was printed in Holland, two important things would happen that would mark Reichel's personal life and anthropology in Colombia. The first is identity laundering. On the flip of the book, it is written that Reichel "was born in Austria, was educated in Vienna, Munich, and at the University of Paris where his studies were interrupted by the war." In this way, Reichel constructs his name and creates his own past, as he was an active part of the fascist groups responsible for the war. The second would be the ratification of the idea that the level of chiefdoms was reached in Colombia, that is, societies with surplus production and centralized powers. This, according to the author, only occurred in northern Colombia in the Tairona chiefdoms and in the center of the country with the Muisca chiefdoms.

If a summary of Reichel's contribution to Colombian anthropology is made, it is clear his interest in systematizing time and space that no one dared to question until well ahead the 1990s. His contribution to the understanding of shamanism, arguing for a country like Colombia, that the use natives give to hallucinogens, could originate certain policy that would take the State, from the criminalization of consumption to its acceptance as an anthropological phenomenon. Undoubtedly, this agenda ceases in a certain way at the end of the 1960s when Reichel presents his resignation letter to the directors of the Universidad de los Andes, at the Department of Anthropology that he helped build, pointing out that the students did not want to benefit from a *pensum* where a matrix was not inserted to position anthropology as a tool to support the claims of social movements, especially indigenous people; this was something he was not willing to accept.

It should be noted that on the situation of indigenous communities, which was very tense in the 1950s because of the murder of indigenous

leaders in the southwestern part of the country claiming their land return, Reichel and his wife were quite cautious because in some way they did not want to hurt the susceptibilities of a state elite whose officials wished that the indigenous situation should not be denounced. Reichel and his wife made a decision, and they knew the integration of the indigenous people was inevitable, so it was necessary to access the possible benefits of a life-saving anthropology (Dussán 1977). This marked a huge gap in Colombian anthropology because many anthropologists took the opposite path and became activists in the indigenous movements and, in some cases, helped consolidate processes that included land return and the release of indigenous leaders who were imprisoned for activism.

At present, Reichel-Dolmatoff's work is received by the new generations of anthropologists in two senses. In the first sense, what is acknowledged are his attempts at visions of time and space on a large scale, which gave, in the end, heuristic elements for the understanding of the pre-Hispanic past. In the light of the criticism established by processualism, this inheritance is seen as a very representative sample of the paths of cultural-historical archaeology and its emphasis on migration as an explanatory mechanism of cultural change. There are even some archaeologists who take Reichel's periodifications to the letter and believe that there really was an evolutionary sequence in northern Colombia. In the second sense, ethnographers have been more critical than archaeologists and have made a revisionist analysis of Reichel's work (Serje 2008). In the results of this review, it is clear that Reichel represented the Kogui as environmentally sustainable societies governed by a sort of elite with ancient knowledge. As shown above, these ideas were quickly taken by Reichel's disciples who even tried to recreate in the Sierra Nevada de Santa Marta a pre-Hispanic utopia of environmentally sustainable societies, using the descriptions of the Kogui temples that Reichel made, as models of the new villages (Serje 2008).

The chronicles written in the colony told stories about the powerful antediluvian tribes, the reading of these chronicles by American archaeologists and their attempts to generate archaeology collections from South America and Reichel-Dolmatoff's use of these ideas when he founded the Ethnological Institute of the Magdalena, were elements that fostered the conditions of possibility of northern Colombia archaeology. Through this schizoid logic (Gnecco 1999), the indigenous of the past were presented as good, ecological artists, and the indigenous of the present were conceived as mere vestiges of pristine cultures that had to be registered before their disappearance.

At present, Reichel's inheritance is debated between two fields. On the one hand, there is a series of revisionists who, from the academic point of view, have shown the limits of Reichel's work, especially his assertion of the existence of social complexity. On the other hand, there is a series of anthropological debates about whether the idea of Tairona-Kággaba continuity should be assumed. In this regard, some voices indicate that this continuity is an imperative of the indigenous social movements of northern Colombia, who see in these postulates the principles of legitimacy for the territorial autonomy they claim. On the other hand, the deconstructionist heritage in anthropology has shown how these equations were built in conditions of possibility where otherness was possible to be narrated as long as it was ecologically friendly. Some scholars point out that these deconstructions were the response that critical anthropology made to the recognition of colonialism in ethnographic texts (Gnecco 2013, 13), which denounced colonialism only in the text and not in practice. Today the agenda, of course, is defined by the role that anthropology and archaeology must play in relation to the collectivities they describe. This debate is certainly relevant because indigenous groups increasingly question the fact that their ethnographic representation be a matter of experts.

In northern Colombia, the indigenous organizations, which include the Kággaba, have started their own self-representation agenda, so Reichel-Dolmatoff's work is also having its internal review. Undoubtedly in the present times, an

ethnographer, in the manner of Reichel, would be impossible because, even, access to the territory could not be given without the permits that must be managed with the indigenous authorities. Even the agenda has gone a little further, and some indigenous leaders are demanding that metropolitan museums return the objects that were taken by collectors at the beginning of the twentieth century. This is how today the Ethnographic Museum of Berlin is arranging the return of two Kággaba masks stolen by Konrad Theodore Preuss at the beginning of the twentieth century (personal communication Cabildo Gobernador Santos Sauna, 2017). This agenda of repatriation claims is happening together with a gradual increase in the control that the Kággaba have begun to have over archaeological sites such as the famous Pueblito Chairama village in the Tayrona National Natural Park in the city of Santa Marta, Colombia.

In this milieu of local communities' empowerment, in addition to the processes of touristification that are occurring on a global scale, Reichel-Dolmatoff's readings will be variable, but undoubtedly, these will be a mandatory reference for the historical knowledge of northern Colombia.

Religion in Islamic Archaeology

Andrew Petersen
School of Archaeology, History and Anthropology, University of Wales Trinity Saint David, Ceredigion, UK

Introduction

As an area of enquiry specifically concerned with one of the principal world faiths, Islamic archaeology has developed mostly within a secular tradition, and the attention paid to religion is fairly limited. The reasons for this are complex and have much to do with the development of archaeology as a secular field of enquiry in Europe and America. The majority of archaeologists working on Islamic material to date have been non-Muslims who perhaps felt ill-qualified to remark on the religious implications of their finds. In addition as with all world religions, there is a potential conflict between the revealed truth of the scriptures and the revelations of archaeology. While this has never become a major obstacle for Islamic archaeology, the scope for potential misunderstanding has meant that issues concerning the origins of the faith have generally been avoided. With these limitations in mind, archaeology has made some important contributions to the study of Islam both as a religious practice and as a diverse set of beliefs. One of the challenges of Islamic archaeology is to acknowledge the profound sense of unity within the faith while also demonstrating the diversity and variations from contemporary established beliefs.

Definition

The study of Islam as a religion may be firmly placed within the wider concept of the archaeology of religious belief as defined and characterized by Insoll (1999). The importance of this approach is that it does not seek to comment on the validity or otherwise of beliefs but rather investigates the material culture(s) of the religion as expressions of the faith. This approach differs from that of comparative religion where beliefs and practices in one religion are compared to and often equated with those of another faith. While the comparative view allows an overview of religious developments, its tendency to generalize and assumption of an interchangeability of belief both deny the agency of the individual and assume a superior position for the investigator.

As a field of enquiry, Islamic archaeology has been primarily concerned with the development and manifestations of Islamic society and culture. Particular attention has been paid to the first three centuries of Islamic civilization when the religion was largely coterminous with a single Islamic state or caliphate. The breakup of the Abbasid caliphate in the tenth century and the resulting political fragmentation created new power blocks based partly on different interpretations of Islam and partly on ethnic and cultural affiliations. The advent of the Crusades in the twelfth century and increasing political fragmentation has meant that much of the historical and archaeological interest in medieval Islam has focussed on conflict either as holy war (*jihad*) or power struggles amongst competing Muslim rulers. However, in the Indian Ocean and Central Asia, both archaeology and history point to societies where the Muslim faith linked traders across vast distances from Cairo to China. The European discovery and exploitation

of the New World coincided with profound changes in the Islamic world. There was a return to larger political entities such as the Ottoman, Safavid, and Mughal Empires, each with their own religious agenda. The archaeology of the recent past in the Islamic world (nineteenth and twentieth centuries) has focussed on an increasing European presence either through trade or colonial encounters as well as warfare.

Historical Background

> [I]n 1343 . . . a resident of Cairo unearthed what he claimed to be an old mosque. A "rowdy" named Shu'ayb could not miss this golden opportunity. He claimed that an apparition revealed to him that the site was an ancient grave of a Companion of the Prophet. . . .Excavations were begun by the commoners, including women, and indeed a "shrine" surfaced. That new discovery further increased the number of visitors, and industrious Shu'ayb organized "guided tours" for fees, in which wives of dignitaries also took part (al-Maqrizi, *Suluk li ma'arifat duwal al-muluk* II: 649–50; Shoshan 1993: 9).

Although Islamic archaeology is currently dominated by a secular European outlook, there are enough examples of Muslims carrying out excavations or studies of ancient material to suggest an archaeological tradition of some antiquity. The example of Shu'ayb (cited above) is interesting because it demonstrates an understanding of archaeological processes by the general public (e.g., buildings collapse, accumulation of material over time, excavation as a means of discovery, and the presentation of archaeology to the public). The other dimension to this discovery is the creation of a religious shrine which according to al-Maqrizi became the site of nightly celebrations until they were discontinued by the religious authorities. Although in this particular instance the orthodox religious establishment did not recognize the shrine, there are many instances where ancient sites were rediscovered and became shrines and centers of visitation. Such activities were particularly popular during the medieval period with prominent examples of rediscovery including the tomb of the Biblical Moses (Nabi Musa) in Palestine, the tomb of Jonah (Nabi Yunus) at Nineveh in Iraq, and Moulay Idris in Morocco. In each case some ancient remains were discovered and associated with some historical event or personage. Moulay Idris is a predominantly eighteenth-century shrine built around the mausoleum of Idris II (r.803–828) whose body was rediscovered in 1308. The shrine of Nabi Yunus is located on the site of ancient Nineveh and was built directly over the ruins of a Christian church. The shrine complex of Nabi Musa was built by the Mamluk Sultan Baybars in 1269 when the grave of Musa was rediscovered. In each case the shrine was built around an ancient relic or site which was both historically plausible and also tangible providing an authenticity which appeared to be lacking in Shu'ayb's discovery of 1343. All of this indicates that there was an empirical and rational understanding of the relationship between the present and the past which is akin to that of modern archaeology.

The Quran provides a basis for understanding the relationship of the past to the present with the story of the cave (Surah 18) in which a number of youths fall asleep in a cave and are awakened 309 years later. When they try to buy food, they are discovered because of their use of old silver coins which were no longer in circulation. The Quran (Surah 7) also explains how the polytheists of al-Hijr (Medain Salih) were punished for persisting in idol worship so that eventually they were killed and their city left in ruins. An appreciation of the processes of change over time is therefore a fundamental part of being Muslim.

One of the earliest and most important examples of archaeological work in relation to Islam was carried out when the Ka'ba in Mecca was rebuilt after its destruction by Ibn Zubayr in 683. Before the Ka'ba was rebuilt, a detailed investigation of the site revealed earlier foundations interpreted as Abraham's original construction. During the process meticulous notes were made including a detailed analysis of the Black Stone at the corner (Peeters 1994: 62–4).

Later on it is evident that there was an awareness of the value of studying ancient remains; thus, the prominent Egyptian scholar 'Abd al-Latif (1162–1231) had a deep respect for the

learning of the ancients and their monuments (Richter-Bernberg 2007). In a statement in his book on Egypt, he summarizes the reason for preserving ancient monuments as follows:

> Antiquities should endure as markers of a remote epoch and reminders of the ages since elapsed. They will serve as witness to the revealed scriptures for the venerable Koran mentions them and their people; thus by seeing them, narration becomes experience and tradition is verified. . . . They indicate something of the forebears' circumstances and conduct, the ampleness of their learning and the clairvoyance of their notions. ('Abd al-Latif, *Akhbar Misr*; Richter-Bernberg 2007: 365).

In addition to scholars directly interested in ancient remains, it is also worth noting that there was a sophisticated historical tradition in the Islamic world with writers such as al-Tabari providing detailed historical accounts of world history. However, perhaps the most sophisticated appreciation of history is found in the writings of the Ibn Khaldun who developed a philosophy of history based on his analysis of historical events in his native North Africa. This historical awareness provided a framework for understanding archaeological remains.

During the nineteenth century European interest in the antiquities of the Middle East and North Africa was often met with suspicion by local Muslims. Part of this mistrust was a feeling that objects of value might be discovered and exported without benefit to the natives of the region. However, there was also a feeling that Europeans would use antiquities to give their own contrasting interpretations of history. In some cases these misgivings were justified and Edward Said's book *Orientalism* documents how Europeans used archaeological investigations as a means of gaining information to help in their colonial endeavors (Said 1978). However, despite the disproportionate military and economic power of the Europeans, the authorities in Muslim countries were able to exercise some control on the activities of foreign (and indigenous) archaeologists. Thus, in 1884 Osman Hadi the director of the Archaeological Museum in Constantinople (Istanbul) enacted the first Ottoman antiquities law placing all excavations under the control of the Ministry of Education (Vernoit 1998). In general however from the nineteenth century onwards, archaeology in the Muslim world was dominated by Europeans (and Americans) who had both the resources and the training to carry out systematic investigations.

As Islamic archaeology developed during the late nineteenth and early twentieth century, the main interests were art and architectural history rather than investigation of Islam as a religion. Archaeologists working on Islamic sites were interested in the retrieval of objects of Islamic art for display in museums and in the recording of monumental architecture. There were however some areas where European archaeologists showed an interest in the religious aspect of Islamic material culture. For example, Conrad Preusser made a study of Islamic shrines and Christian churches in northern Iraq while attached to the German excavations at Babylon in the early twentieth century. In early twentieth-century Palestine, there was considerable interest in Muslim shrines partly because it was thought that they may relate to some Biblical sites and partly because archaeologists working in the Holy Land were predisposed to look at religious aspects of antiquity.

The other specifically religious aspect of Muslim culture that interested nineteenth- and early twentieth-century archaeologists and art historians was the question of iconoclasm or prohibition of figural images. Following excavation of Umayyad sites in Syria and present-day Jordan and Palestine, it became apparent that the religious ban on the portrayal of human figures was not universally applied. For example, semi-nude female figures were painted onto the walls of the bath house at Qusayr 'Amra in Jordan, while at Khirbat al-Mafjar there were stucco figurines of semi-naked women also in the bath house. However, in certain areas and times, the figural ban was implemented, most famously in the 690 s when Abd al-Malik (685–705) replaced figural coinage with purely epigraphic coins (Walmsley 2007: 59–64). For some archaeologists the implementation of the ban on figural images was aimed particularly at Christians and was seen as a sign of Muslim intolerance. For example, John Crowfoot commenting on the damaged mosaics of Jarash

wrote "...all representations of living creatures were ruthlessly destroyed. The sorry way in which the mutilations were repaired shows the wretched plight of the Christians" (Crowfoot 1938: 172–3).

Key Issues

The religious nature of Islamic society expressed through Islamic laws and customs has meant that all areas of Muslim life are potentially relevant to archaeology. However, a number of areas of investigation are of particular relevance to an understanding of the religion. These may be summarized as mosques; *hajj* routes; shrines, mausolea and burials; and *halal* diet.

Mosques

As the most visible symbol of the Muslim faith, mosques are an ideal subject for archaeological research particularly as they have been part of Islamic culture from the start (Figs. 1 and 2). When investigating ancient remains, the presence or absence of a mosque is often the best indicator of whether the former inhabitants had adopted Islam as a religion. It is even possible to get an indication of the possible number of Muslims in a settlement at a particular time. For example, the Byzantine and early Islamic settlement of Shivta in the Negev had three churches and a small mosque attached to one of the churches suggesting a Muslim minority in a Christian town (Magness 2003).

There are however some problems with using mosques as an indicator which may be summarized as (i) the identification of a building as a mosque, (ii) dating the period of construction and use, and (iii) problems associated with investigating mosques still in use.

The easiest way to identify a mosque is by the presence or absence of a *mihrab* which is a concave niche inserted into the wall of the prayer hall to indicate the direction of Mecca and consequently the direction of prayer (*qibla*). Even if a mihrab is not found, the orientation of a building to the *qibla* (direction of Mecca) will suggest that a building is a mosque. However, there are problems with both these indicators. The earliest mosques did not have a *mihrab* in the form of a concave niche.

The first concave *mihrab* was inserted into the Prophet's Mosque at Medina during some restorations carried out by the Umayyad caliph al-Walid I in 706. The date of the introduction of the *mihrab* niche is confirmed by excavations at

Religion in Islamic Archaeology, Fig. 1 Mosque of Sayyid Jamal al-Din at Anau, Turkmenistan (built 1446–1457), destroyed by an earthquake in 1948. Note the decorative dragons either side of the main arch

Religion in Islamic Archaeology, Fig. 2 Kutlug Timur Minaret at Kunya Urgench, Turkmenistan (built between 1321 and 1336). Large minarets such as these were not only a visual symbol of Islam but were also memorials to their founders

Wasit, Iraq, where two mosques were found built one on top of the other. The earliest mosque, dated to the seventh century, did not have a concave *mihrab*, while the later eighth-century mosque had a *mihrab* niche. Similarly the orientation of a building may be misleading because many early mosques were misaligned. In most cases however both the alignment and the presence of a *mihrab* will confirm a building's function as a mosque.

In terms of dating mosque construction and use, often it will be possible to get an idea of the date of a mosque from a foundation inscription. However, in many cases this will either be missing or the inscription may come from an earlier building. In addition the fact that mosques are not used for residential purposes means that an excavated mosque will rarely contain dateable material. Once a site has been designated for use as a mosque, it will tend to retain this function through time. In practice this means that many apparently new buildings are built on older foundations or may even incorporate portions of an earlier structure, which are thus not easily accessible to archaeologists.

Hajj Routes

The *hajj* pilgrimage to Mecca is one of the five obligations held by all Muslims. If a person has the necessary means and is physically able, the pilgrimage to Mecca once in a lifetime is obligatory. Given the rapid geographical spread of Islam from the seventh century onwards, this has meant that a network of pilgrimage routes from all over the world converges on Mecca (Petersen 1994). There have been a number of archaeological studies of these routes most notably the Darb Zubayda from Iraq, the Darb al-Hajj al-Shami from Syria, and the Darb al-Hajj al-Masri from North Africa.

Shrines, Mausolea, and Burials

Shrines, mausolea, and burials are three connected issues within the archaeological study of Islam. Firstly it is worth mentioning that all schools of Muslim thought agree that burials should be simple and that graves should not be marked with extravagant structures. However, in practice throughout the Muslim world, there have been elaborate grave markers and mausolea have been built around the graves of particularly prominent individuals (Fig. 3). Where the individual concerned is thought to have been particularly pious, valiant, or important, the mausolea have often become shrines venerated by Muslims (Fig. 4). There have been many archaeological studies focussing on these issues (Petersen 1996, 1999, 2001). Some draw attention to the fact that shrines provide a religious focus for women, illiterate people, and others who feel excluded from more formal religious practices at mosques.

Halal Diet

Muslims are governed by dietary laws dictating what food is permissible (*halal*) and what is forbidden (*haram*). The most well-known prohibition is against eating pigs, although many other categories of food are restricted. Environmental archaeology can investigate deposits to gain an

Religion in Islamic Archaeology, Fig. 3 Grave of holy man at Kunya Urgench, Turkmenistan, with rags tied to poles indicating the prayers of pilgrims, visitors, and relations. This form of religious practice with links to shamanism is discouraged by orthodox Islam but is widely practiced

Religion in Islamic Archaeology, Fig. 4 Pilgrims visiting the sixteenth-century tomb of Sultan Ali near Kunya Urgench, Turkmenistan

idea of whether a particular society was following Muslim dietary rules (for a discussion see Insoll 1999: 4–107). In southeast Asia the analysis of animal bones has been used to determine at what stages particular communities are converted to Islam (Lape 2005). However, it is known that in certain cases, people describing themselves as Muslim have ignored some of these rules; thus, evidence of wine consumption has been found at early Islamic sites, and it is known that some Sufi sects also drank wine as part of their activities.

International Perspectives

Within the archaeology of religion, international perspectives may be interpreted as the interaction with other faiths. Four examples will be used to indicate how archaeology can inform and in some cases inflame conflicts centering on religious sites.

The partition of India into India and Pakistan in 1948 polarized Muslim and Hindu sentiments, and both countries are still dealing with the consequences. In terms of archaeology and heritage, the most well-known incident was the destruction of the mosque (Babur Masjid) at Ayodhya in 1992 by supporters of the Hindu nationalist party (Nandini 1999). The demolition of the mosque led to rioting in which more than 2,000 people were killed, and the incident still incites violence. The mosque was built in 1528 by one of the generals of the Mughal Emperor Babur on a site which according to Hindus marks the place where the Hindi deity Lord Ram was born. In September 2010 following an archaeological investigation which revealed an earlier (Hindu?) building, custody of the site was divided between Muslims and Hindus.

The second example is the Dome of the Rock in Jerusalem which is believed to stand on the site of the Jewish temple which had been destroyed by

the Romans. The bitter conflict between Israel and Palestine has focussed on Jerusalem and in particular on the area of the Haram al-Sharif. For Muslims this is the third holiest shrine and the destination of Muhammad's miraculous night flight from Mecca (Necipoğlu 2008). The intensity of the conflict is such that there have been several attempts by Jewish extremists to destroy the building. The plans, a model and even actual fittings made for the new temple, which is planned once the Dome of the Rock has been destroyed, already exist.

At Bamiyan in Afghanistan the situation was reversed when the Taliban destroyed the two monumental Buddhas carved into the cliff. Prior to the destruction the Taliban publicized their intention finally blowing up the statues in 2001. The event was presented as an attack on figural images and idol worship which was intolerable to Muslims. However, archaeological research has indicated that Bamiyan was inhabited by a Muslim population for over 1,000 years without problems (Morgan 2012: 81–130).

Finally it is worth considering the mosque of Cordoba in Spain built by the Umayyad caliph Abd al-Rahman in 784 on the site of a church. The mosque was gradually enlarged over a period of 200 years and became one of the most celebrated mosques in the world (Khoury 1996). Cordoba and the mosque were reconquered by the Christians in 1236, and the mosque was gradually converted into a cathedral. In the sixteenth century major construction work within the former mosque saw the addition of a nave which while visually intrusive is thought by many to have preserved the building from the excesses of the Inquisition which may otherwise have called for the destruction of the entire building.

Future Directions

A number of difficulties arise when considering the relationship between Islam and archaeology. Three of the most pressing issues are pre-Islamic and Quranic archaeology, Muslim sects and divisions, and Islamic practice in archaeology.

Pre-Islamic and Quranic Archaeology

The general perception of Islamic archaeology is that it investigates the archaeology of Muslim societies from the 630 s to the present; however, to some extent it must also consider the pre-Islamic archaeology of Arabia. As a functioning religious center, the *haram* at Mecca is off limits to archaeology, yet we know a certain amount about the shrine from early Arabic authors (Nevo and Koren 1990) which gives a window on to the pre-Islamic archaeology of the site. Similarly there are some sites such as al-Khaf al-Raqim in Jordan (Walmsley 2007: 141–4) which have been identified as the site of the story of the cave as mentioned in the Quran (Surah 18). Both of these examples are fairly unproblematic; however, there is the potential for an archaeological investigation to encounter material which may challenge the orthodox religious view.

Muslim Sects and Divisions

Because Islam is a living religion and because extremists have drawn considerable attention to their faith, the archaeology of Islam is faced with considerable challenges. On the one hand as social scientists archaeologists must adopt a neutral detached approach to the field of study, yet it is inevitable that in some cases a particular view will be regarded as support for a particular position. Although Muslims see themselves as part of a single Islamic community (*ummah*), in practice there are many sects, ethnic and cultural affiliations, as well as political configurations which cause major divisions. The problem for the social scientist is that there is considerable pressure to regard any one of these forms as the normative Islam from which other forms deviate. This question is becoming increasingly important as communications improve and the ability of wealthier nations to encourage their interpretation of Islam increases. One of the main sectarian divisions is between *Shia* and *Sunni* Muslims, although there are also other groups which have political dimensions such as Sufis, Salafis (Wahabis), and Ibadis. In addition there are groups such as the Bahais and the Druze which originated within

Islam but are generally regarded as outside the recognized religion.

Islamic Practice in Archaeology

While the majority of nineteenth- and twentieth-century archaeologists investigating Islamic culture were from a secular Christian or Jewish background, the number of Muslim archaeologists working either in the field or as academics is increasing steadily. Should the religious faith of an archaeologist matter? And is it preferable to have Muslims investigating Islamic sites? In most cases the personal beliefs of the archaeologist will be irrelevant, although in some cases it has been argued that only Muslims are fit to excavate mosques and interpret Islamic culture. Such views are obviously extreme and would lead to a situation where the investigation of the archaeology of another religion or culture became effectively impossible. However, such views may be regarded as a reaction to the European-dominated Orientalist narrative which first characterized Islamic archaeology.

Introduction

Archaeologies of Greek religion may be divided into three categories: the analysis of artwork, the publication of sites, and the categorization of ritual practices. Topically, boundaries between these are permeable; methodologically, all of them build on the integration of material, epigraphic, and textual evidence. This relationship to textual evidence both characterizes and problematizes Greek archaeology, which is often criticized for its theoretical naïveté, its distance from anthropological archaeologies, and its striking conservatism (Dyson 1993; Morris 1994; Whitley 2001: 11–59; Barrett 2015). These characteristics are the result of a long intellectual and political history. The identification of ancient Greece as the fountainhead of western civilization served the nationalism of Greece as it emerged from Ottoman rule: it helped secure the support of European nations, and the archaeological service was one of the first departments of the new government to be established (Hamilakis 2007). The "glory that was Greece" informed the cultural ambitions of the 17 nations who established archaeological schools in Athens; the tradition favored a focus on classical sites known from Greek historical texts and shaped a culture-historical approach to the interpretation of archaeological materials. The culture revealed was deemed a priori unique and so beyond comparison with other nations. The great ritual centers were among the sites apportioned to these foreign schools. Greek religion was already well established as a field of textual inquiry when these excavations commenced. The rich epigraphic record from these sites, which named figures familiar from myth and history, reinforced the unproblematized relationship with textual sources and delayed the emergence of a critical body of theory regarding the relationship between the textual and the archaeological record. Although calls for greater integration of textual and material evidence appear in many surveys of Greek religion, literary continues to outweigh material evidence in the key texts for the field (Hägg 1992; Osborne 1994; Morris 2000; Burkert 2011: 1–7). Archaeologists working on Greek cult, moreover, are rarely located in anthropology or religion departments, more frequently in art history, classics, or history – where publications focused on iconography, architectural history, or the relationship of finds to Greek and Latin texts speak most clearly to colleagues judging questions of promotion and tenure.

The archaeology of Greek cult is thus suspended between at least four academic disciplines – classics, art history, religion, and anthropology – and burdened with political and cultural expectations. Some of the most intriguing new work in the field, however, emerges precisely from the efforts to close the gap between these traditional divides. The mid-1970s saw the emergence of critical perspectives on the history of the discipline; these insights are combined with new technologies, increasingly accessible databases, and a more robust theoretical framework for the relationship between the textual and the archaeological record. These are reshaping the boundaries of artifact, site, and ritual studies within Greek archaeology, at the same time that the major locus for publications remains traditional classical rather than anthropological journals (Kindt 2011; Hamilakis 2011).

Definition

The archaeology of Greek religion may be defined as the investigation of material evidence for ritual

action carried out by individuals who identified themselves as Greeks. Ritual actions are defined here as symbolic, traditional communications designed to bridge the human and divine worlds: there is no ancient Greek category which corresponds precisely to our term "ritual," and while debates about the relationship between religious and secular ritual have appeared in classical studies, these lie beyond the framework of this essay (Bremmer 1994: 38–54; Bell 2007). The chronological and geographical boundaries of Greek religion shape its archaeology in both theoretical and practical ways. The chronological may be situated between Prehistoric and Bronze Age on the one hand and Christianity on the other; boundaries between these are permeable. Continuity from Bronze Age use is attested at sites such as the cave of Zeus on Mount Ida (Watrous 1996) and the sanctuary at Syme (Lebessi 2009); Mycenaean burials provided the focus for historical hero cult from the eighth century on (Antonaccio 1995); and Hellenistic architects in the sanctuary of the Great Gods of Samothrace constructed a false door in the style of the late Bronze Age mainland (McCredie 1974). The archaeological signatures of prehistory were thus part of the intellectual landscape of Greek ritual practice into the historic period and provide an ancient context for the reinterpretation and usurpation of the past (Voyatzis 1992; Naoum et al. 2004; Prent 2005). Christian responses to pagan traditions translated into desecration and destruction of classical material, their transformation into new sacred spaces and images, or their decontextualization and redistribution as spolia (Pollini 2007; Hahn et al. 2008). The most violent behavior, more articulate than simple destruction, carved crosses into ancient statuary, or smashed faces, breasts, and genitalia of ancient statues, while leaving the remainder intact as a statement of Christian triumph. More nuanced responses transformed the pagan symbols into Christian iconography, studies of which engage with textual as well as material evidence (Elsner 1995). The transformation of traditional temples into churches begins some 200 years after the Theodosian code of 391 dictated the closing of pagan sacred spaces; causes for the delay may be reflected in legislation, contemporary with the code, which recommended the preservation of the temples as symbolic and practical structures. Examples of these architectural conversions include the temple of Aphrodite in Aphrodisias in Caria, the Parthenon, the Hephaisteion, the Asclepeion, and the Erechtheion in Athens (Ward-Perkins 1999; Arce 2009). The reuse of architectural materials as spolia was a pagan as well as a Christian practice: recent publications explore the semantic range of such repurposing, from appropriation to nostalgia to triumphalism to exorcism (Brilliant and Kinney 2011).

Geographically, sites for Greek cult are found far beyond the Greek mainland or its islands. Greek settlements stretched from the Black Sea in the north to Egypt in the East and Italy in the west. The geographic range of study means that excavations relevant to Greek religion are shaped by the political realities of a number of Mediterranean countries. Braund describes the great personal risk undertaken by local people who aided him in his archaeological explorations in the 1970s around Colchis; Davis describes the fieldwork made possible, including the excavation of an archaic temple to Apollo, after Albania opened its doors to the outside world in the mid-1990s (Braund 1994; Davis 2012: 65–68). The opening of former Soviet Bloc countries redefined the study of Greek religion in the regions around the Black Sea, where some 90 colonies were attributed to one Greek city, Miletus, alone (Tsetskhladze 2006/2008; Muratov 2015). Theoretical frameworks for cult in these regions were initially shaped by studies of Greek colonization which began in the 1980s. These emphasize cult as a mechanism of cultural identity and mediation at ethnic, political, and territorial boundaries. Archaeological foci include the establishment of hero cults, the political uses of temple and monumental architecture, signals of cultural assimilation in funerary ritual, and the emergence of syncretistic celebrations. Sicily has been an especially rich locus for this work, as a place where Greeks interacted with indigenous cultural groups as well as the Phoenician settlers who could serve as both partners and competitors in their colonizing goals (Kleibrink et al. 2004; Marconi 2007;

Shepherd 2015). Intellectual models for Greek colonization have moved from models of Greeks-v-Barbarians and center-periphery toward post-colonial models of hybridity and mediation. Network models suggest that symbolic expressions of Greek identity are strongest at the greatest remove from territorial centers, reinforcing the importance of ritual at the edges of the Greek world (Malkin 2011); postcolonial and globalization theories offer light on identity construction in a profoundly connected Mediterranean world (Hodos 2010).

Historical Background

An archaeology of Greek religion may be argued to have its birth either in the early Renaissance or after the 1970s. The date depends on whether this archaeology is defined by the use of the site in antiquity or by a deliberate methodology and theoretical framework aimed at recovering the religion of the site. The former, which we may consider an incidental archaeology of cult, characterizes much of the earliest archaeology in Greece. The great sanctuaries of Greek history – known from ancient texts and confirmed by inscriptions – were objects of exploration as early as the fifteenth century, when the early Renaissance antiquarian Cyriacus of Ancona toured the Greek world, sketching monuments and recording inscriptions (Belozerskaya 2009). The historical functions of Greek sanctuaries as sites for competitive display also made them treasure houses of sculpture, architecture, finely worked votive objects, and the inscriptions which were the objects of particular interest for these first explorers.

The nineteenth-century excavations of these sites reflect a range of European intellectual trends – Romanticism, connoisseurship, nationalism, and *Altertumswissenschaft* – which came into being during the nearly four centuries that Greece was ruled by the Ottoman Turks (1460–1830). Romantics of the eighteenth and nineteenth centuries idealized the ancient Greek world and approached archaeological sites as the embodied past of a perfect heroism, now conquered and crumbling. Enthusiasm for the ruins, and the conviction that they offered access which texts could not, drew Romantic travelers, Goethe among them, to Ottoman Greece. J.J. Winckelmann, deemed the father of Greek archaeology (1717–1768), shared some of the conceptions of the early Romantics, if not their itineraries. He never went to Greece but proposed the first schematization of Greek art history based on his observations of objects in Rome. Winckelmann identified four historic and aesthetic stages of Greek art history, and the principle that changes in style was the key to chronology. His conjectural model received reinforcement from the museum collections which began to grow in earnest in the eighteenth century, when European nobles rushed to collect ancient Greek vases and sculpture. War between France and Britain in the eighteenth century further escalated the appetite for building private collections and public museums, as bitter military conflicts translated into cultural competition. Philhellenic sensibilities also spurred military and political support for the Greek war of liberation against the Ottomans and, subsequent to liberation, to the establishment of archaeological schools in Athens – the French in 1846, German in 1874, British 1876, and American in 1881. The major excavations run by these schools included the sanctuaries of Delos, Delphi, and Olympia. The excavations appear innocent of theory or agenda: the objectives were to excavate, preserve, categorize, and publish the finds. This apparent objectivity was underwritten, however, by the Hellenism which emerged in the Romantics, informed the tradition of the Grand Tour, fed the connoisseurship of the eighteenth century, and became an arena for the competitive nationalism of the nineteenth century (Dyson 1993; Morris 1994; Whitley 2001: 3–42).

The question of ritual practice per se was of minimal or no interest to these early explorers, despite the centrality of prophecy to Delphi, the cult of Apollo to Delos, and ritual competition to Olympia. "The glory that was Greece" did not include its paganism, which was either opposed to Christianity or reconciled with it through allegorizing explanations. Critical approaches to an archaeology of cult did not materialize in classical

archaeology until the 1970s, as part of the effort undertaken by some practitioners to redress the distance between classical and world archaeologies. This distance was not inevitable: the fields among which the archaeologies of Greek cult are now distributed – archaeology, classical studies, anthropology, and religion – were at their beginnings more closely tied to each other (Rowe 1965; Varto 2018). An education in classical and Biblical texts was the general rule for all earlier practitioners of archaeology, and the Romanticism and nationalism which shaped Greek archaeology shaped anthropology as well (Renfrew 1980; Morris 1994). Several historical junctures are identified as the moment at which classical and other archaeologies diverged. Morris points to the 1870s, when classical archaeology became a subdiscipline of classics and thus removed from the broader archaeological world (1994). Whitley notes the conflict between prehistoric and classical archaeology as a cause of the separation. This was exemplified in a paper delivered by V.G. Childe in 1943, in which he berated classical archaeology, and his teacher Beazley in particular, for its simultaneous enthusiasm for fine arts and indifference to the tools and households which were the real record of history. This initiated a separation of classical from world archaeology during the three decades when world archaeology most flourished, from 1945 to 1975. The separation grew even deeper in the 1960s, when classical archaeologist actively retreated from the new theoretical dimensions explored in other archaeologies. The paradigm for classical archaeology in this period is Beazley's attribution studies, which linked Renaissance humanism with Winckelmann's conjectural scheme and a scientific fastidiousness in matters of detail; the field drew its prestige from classics and its audience from those who read the ancient texts (Whitley 2001: 12–16).

If classical archaeology was absent from theoretical advances in world archaeology between 1870 and 1970, it was also engaged only peripherally in the theoretical advances in Greek religion. Myth, as preserved in literature, was fundamental to the study of Greek religion from the time of the Church fathers. These approaches changed in the early nineteenth century. Lobeck's massive, querulous volume, *Aglaophamus* (1829), demonstrates a determination to gather, critique, and chronologically order all the ancient sources for Greek myth and mystery cults; it may be deemed a philological analogue to the "science of antiquity" which defined German excavations at Olympia. In the last quarter of the nineteenth century, overseas colonies, reports from missionaries, and the emerging discipline of ethnography brought paradigms for comparative study, evolutionary models, and a focus on ritual to British and German scholars of Greek religion. The Cambridge Ritualists emerged in Britain, among whom Jane Harrison was the most archaeologically focused (Harrison 1890; Ackerman 1991). In Germany, Mannhardt (1875) compared European peasant customs with ancient traditions and postulated agricultural festivals of fertility and annual renewal; the Cambridge scholar Frazer extended the range of comparanda to include all ethnographically known cultures, as well as ancient Greece and Rome (Frazer 1890–1915). Dieterich, a follower of Mannhardt, founded the *Archiv fur Religionswissenschaft* in 1904 and thus the platform for an independent discipline of the history of religion (Burkert 2011: 1–7). Durkheim's sociology and the discovery of psychoanalysis both impacted studies in Greek religion as well. Gernet brought Durkheimian sociology to Greek religion and to the group known as the Paris school, led by Vernant and Detienne, who inaugurated a trend toward the application of structuralism and functionalism in studies of Greek myth and ritual in publications from the 1960s through to the new century. Detienne (2005) provides a conspectus of these discussions. Kerenyi applied concepts of archetypes developed from Jungian psychoanalysis to Greek myth (Kerényi and Jung 1941; Kerényi 1976; Schlesier and Sanchiño Martinez 2006); Caldwell employs Freudian analysis (1990); E.R. Dodds, in *The Greeks and the Irrational* (1951), invited investigation of those portions of Greek religion not represented in the shining marble edifices of Athens.

The archaeology of Greek cult remained as aloof from these developments as it did from

world archaeology. Changes of the last four decades, however, have begun to close both of these divides. Regional studies balance the traditional overemphasis on Athens; a shift away from attribution studies and toward mentalities has initiated fresh conversations on the insights into ritual provided by vase painting (Hedreen 2011; Bundrick 2014). Burial rituals are integrated with cultural constructions of space and memory, ethnic identity, and quantitative analyses (Arrington 2015; Kelley 2012; Shepherd 2005; Houby-Nielsen 1995). If these represent a lessening of the divide between Greek and world archaeologies, internal divisions within the field have also been lessened through the creation of several key resources. The online publication of the *Supplementum Epigraphicum Graecum* provides a searchable database for all Greek inscriptions; the *Epigraphic Bulletin for Greek Religion* offers an annual guide to new inscriptions relevant to Greek cult, published since 1991 in the journal *Kernos*. The *Lexicon Iconographicum Mythologiae Classicae* provides topical introduction to the iconographic traditions for Greek and Roman divinities and heroes (Boardman et al. 1981). The *Thesaurus cultus et rituum antiquorum*, published since 2004, offers up to date introductions to a range of Greek cult types; the *Chronique archeologique* offers an annual account of new archaeological discoveries relevant to Greek cult, published in the journal *Kernos* since 2001. There is as yet no established canon of theory and method for an archaeology of Greek cult, though Renfrew provided one in 1985 for Bronze Age studies (Renfrew 1985; Osborne 2004b). The changes of the last four decades have not resolved the distance between classical, prehistoric, and world archaeologies. The relationship between Greek religion and Greek archaeology continues to be uneven, and the footprints of the field's earliest days linger even in the newest approaches. Whitley, for example, has noted that the Romanticism that shaped the emergence of Greek archaeology appears in new survey and landscape studies and suggested that the same idealization may lie behind the relative absence of economic and environmental archaeology in classical archaeologies (2001: 47). An archaeology of Greek cult is still evolving: it is characterized most by its diversity and is apprehended through a range of examples rather than an established canon.

Key Issues

Issues both perennial and current within the archaeology of Greek cult demonstrate the range of advances made in the 1980s and beyond. An exploration of sacred space, and an overview of two ritual types, provides a framework for a number of the recent debates and new methodologies. A more complete list of ritual types and foci of investigation may be found in Motte et al. (1992, 1998).

Greek sacred space was defined by a range of factors, from natural sacrality to political need. Caves, grottos, and mountain peaks were among the natural spaces which were considered either inherently numinous or the location of prehistoric celebration. More recent studies demonstrate that these sites were neither necessarily prehistoric nor natural and served a range of ritual and intellectual functions. Dillon (1997a) surveys the textual evidence for the mentalities which inform these choices; the cave sanctuary in Sphakia, southwest Crete, demonstrates use into the Hellenistic and Roman periods (Francis et al. 2000); Hellenistic Rhodians constructed artificial grottoes which aligned with the city's grid plan and provided loci for the display of votives to unknown gods (Rice 1995). Sacred gardens offer analogous evidence for the man-made creation of naturally numinous spaces, rituals in which mediated between the human and the divine as the settings mediated between anthropogenic and natural landscapes (Barnett 2007). Approaches from cognitive psychology and neurosciences have now been brought to the investigation of cult in caves: Ustinova's (2009) study integrates these perspectives with archaeological, historical, and textual evidence.

The location of sanctuaries in the civic and natural landscapes received significant theoretical boost in 1984 with de Polignac's study linking sacred space to the emergence of Greek city-

states: temple and sanctuaries, he argued, were locations for city-states to contest territorial boundaries and achieve mediation with their neighbors. A flood of studies followed, including Schachter (1992), Alcock and Osborne (1994), and Cole (2004). The focus on sacred space has extended, in the first decade of this century, to studies of landscape: religious applications include the definition of sacred landscape, its memorial, metaphoric and ritual uses, and the balance of ritual and practical functions. Scheid and de Polignac provide an overview of the problems and potentialities of this discussion (2010); Gkiasta offers a review of how these methods and theories have been applied to Crete (2008); del Olmo applies the questions of landscape and religion to southwest Arcadia and Sicily (2005a, b, 2010); Olshausen and Sauer (2009) offer a collection of 28 papers from a 2005 colloquium. Both survey archaeology and regional approaches to Greek religion inform these approaches to sacred space which extend beyond the confines of a single sanctuary. Romano demonstrates the contribution of survey to the sanctuary of Zeus at Mount Lykaion (2005); del Olmo provides an exploration of the impact of regional approaches to Arcadian religion (2005b).

The date at which sanctuaries emerged in Greek history has been a matter of energetic debate. The first elements have been identified in the eighth and ninth centuries BC; investigations engage questions of the relationship between sacred space, political identity, and the definition of boundaries. Morgan's studies at Olympia offer a Peloponnesian case for this emergence; Simon provides an Ionian; Mazarakis Ainan has argued that temples replaced the homes of rulers as locations for cult around the first half of the eighth century (Sourvinou-Inwood 1993; Morgan 1993; Simon 1997; Mazarakis Ainan 1997). Østby provides an annotated, geographically arranged bibliography on research on Greek sanctuaries 1965–1993, including directions in architectural studies which define the functions of discrete areas within the temples (1993). Scott surveys the productive attempts over the last three decades to integrate temples not only within architectural typologies and ancient texts and inscriptions but within their landscapes, ritual types, and moveable finds (Scott 2015).

The boundary of sanctuary space was defined by both physical and behavioral means. Physical boundaries consisted of either a built wall or natural features: see Bergquist (1967) for a study of the definitions of the Greek *temenos* and Patera (2010a) for analysis of the terminology brought to sacred spaces. The "sacred laws" which regulated behavior in ritual areas constitute one of the most important bridges between written and archaeological evidence for sacred space. Lupu's (2005) publication offers an update to Sokolowski's canonical works of 1955, 1962, and 1969; Parker's (2004) essay considers the meaning of the term "sacred law"; Brulé (2009) offers a collection of essays exploring the dynamics of ritual regulations. Calendars varied from one city-state to another and reflect the festivals, sacrifices, priesthoods, and civic groups responsible for the performance of rituals which held the state together (Carbon 2015). Lambert (2002) offers the first full edition of the Athenian sacrificial calendar; Robertson (1999) uses the calendar to cast light on the Eleusinian mysteries.

The effective boundary of sacred space extended beyond the sanctuary walls, and two recent foci – processions and pilgrimage and the territories owned by the temple for economic gain – integrate archaeological and historical data in their investigation. Graf notes that studies of processions lapsed after the start of the century and proposes a distinction between centripetal and centrifugal (Graf 1996); Connor provides a survey of methodology (1987); Herda provides a detailed analysis of the new year's procession between Miletus and Didyma (Herda 2006). Travelling to internationally recognized oracles, festivals, and mystery sites extends the question into the broader Mediterranean; comparanda are drawn from Christian pilgrimage and have particular focus in late antiquity (Dillon 1997b; Elsner and Rutherford 2005; Kristensen and Friese 2017). The economic functions of the Greek temple include the owning and leasing of land, sale of priesthoods, the production of goods in the sacred area, and the cost of temple construction (Salmon 2001; Davies 2001; Dignas 2000, 2003). Festivals

and emporia demonstrate the integration of ritual activity and economically beneficial exchanges (Naerebout 2001; Demetriou 2011). The publication of conferences from 1990 to 2005 offers overviews of the state of the question (Linders and Alroth 1992; Nielsen 2009).

The altar is one of the most essential elements of Greek sacred space, and sacrifice has been the object of a range of publications in the first decades of the twenty-first century (Graf 2002; Knust and Várhelyi 2011; Naiden 2013). Greek cult practice knew both elevated altars and offering pits. The elevated types range from the mounds formed of the remains of previous offerings, consisting of ash, bone, or horn, to the architecturally elaborate monumental altars of the Hellenistic period. Altars made of ash and bone now appear to be more common than previously imagined: examples include the massive ash altars of Zeus at Olympia and at Mount Lykaion (Hägg 2000; Romano 2005). The archaeology of monumental Hellenistic altars on the order of the altar of Zeus at Pergamon has a continuing position in art historical and architectural study. Webb (1996) includes the altars in her study of Hellenistic architectural sculpture; Scholl (2009) explores arguments for the altar of Zeus as an imaginary palace. The ability to distinguish functional differences based on altar types is an ongoing debate: the traditional hypotheses of raised altars for Olympian gods, offering pits for chthonic gods and holocaustic sacrifice, have been challenged (Kearns 1992; Kron 1999; Ekroth 1999, 2002, 2001; Boehringer 2001; Stratiki 2002; Patera 2010b). The frequent representation of sacrificial scenes on vase paintings makes iconography a major resource for altar studies, which may be devoted to typology (Rupp 1991a, b) as well as to ritual practice (van Straten 1995). The divide between archaeological and textual studies of Greek religion is most thin in connection with sacrifice and feasting. These include anthropologically informed hypotheses for the origins and function of sacrifice (Burkert 1983), analyses of sacred violence (Girard 1972; Georgoudi et al. 2005), and the contributions of the Paris school, drawing on structural analysis of myth and history (Vernant and Detienne 1979; Faraone and Naiden 2012). The study of sacrifice is also one of the relatively few areas in which faunal analysis has come to play a role in the archaeology of Greek cult: overviews are provided in Reese (1997) and MacKinnon (2007); Bookidis et al. (1999) bring these technologies to the analysis of the cult of Demeter and Kore at Corinth. Essays collected in Georgoudi et al. (2005) provide a conspectus of current approaches to sacrifice in Greek religion, against which the archaeological studies may be measured; articles in Mehl and Brulé (2008) emphasize archaeological and iconographic approaches to sacrifice. Among the most theoretically bold approaches – and the most distant from the long history of an isolated classical archaeology – is the volume *Architecturer l'invisible*, in which altars are explored in Greek, Assyrian, Medieval, and ethnographic contexts (Cartry et al. 2009).

Sacred space was also defined by votive practice. Archaeological approaches have moved from collection and cataloguing of finds to considerations of function, regulations, and economic impact. Votives in the form of body parts are traditional inclusions in shrines of healing divinities and offer exceptional insight into the intent of the dedicator; studies of the production of votives on-site reshape the conception of the Greek sanctuary as experienced in antiquity. Key publications in the recent discussions include F. van Straten (1981, 1990), Bodel and Kajava (2009), and Prêtre and Huysecom-Haxhi (2009). Day has drawn attention to the interactive potential created by inscriptions on dedicated objects; Osborne positions Greek votive practices within the world archaeological perspective (Day 2010; Osborne 2004a). The "material turn" has brought to bear a range of new approaches to these objects as agents, which are both socially constructed and actively shape the contexts in which they function (Meskell 2005).

Among the many ritual types identified within Greek religion, hero cults and rites of passage demonstrate the confluence of methodologies and research agendas which have enlivened the archaeology of Greek religion over the past three

decades. In studies of hero cult, the uses of Homeric poetry exemplify the more nuanced relationship between text and archaeology which turns the classical reliance on texts from a liability into a critical asset. Current debates focus on political function of hero cult, its distinction from tomb and ancestral cult, the ancient reuse of Bronze Age remains, and the potential to identify a distinctive sacrificial practice (Popham et al. 1982; Morris 1988; Alcock 1991; Antonaccio 1994; Whitley 1994; Ekroth 2002). The ritual type identified by van Gennep over 100 years ago as Rites of Passage has long been applied to studies in Greek religion. While its heuristic value has been vigorously debated (Dodd and Faraone 2003), it continues to provide a framework of investigation for rituals at the sanctuary of Artemis at Brauron, athletic competitions for both genders at Olympia, analyses of weddings and funerals, and studies of data from Crete from the Bronze Age through the Hellenistic period (Kahil 1983; Koehl 1986; Sourvinou-Inwood 1988, 1990; Barringer 1991; Shapiro 1991; King 1993; MacGillivray et al. 2000; Scanlon 2002; Serwint 1993; Erickson 2009). These studies combine archaeological, iconographic, epigraphic, and historical evidence. Caveats regarding the historical tenability of van Gennep's paradigm must be balanced against the extent to which the model succeeds in bringing together a range of ritual types and examples and so furthers the movement toward comparative study whose absence once characterized the archaeology of Greek cult.

International Perspectives

Because of the role of non-Greek nations in Greek archaeology, a range of international voices has characterized the archaeology of Greek religion from the onset. Reactive or dissident schools have emerged in Cambridge, Paris, Hamburg, and Naples, each of which offers some contribution to a new archaeology of cult. Cambridge emerged as a center for theoretically rich studies, led by publications focusing on the emergence of the state and social complexity and the use of quantitative analysis (Snodgrass 1971, 1977; Renfrew 1972; Morris 1987; Morgan 1994). The Theoretical Archaeology Group, begun by the universities of Sheffield, Cambridge, and Southampton in 1979, provides an ongoing meeting ground for the debate of archaeological theories. Centers for structural studies emerged in Paris and Hamburg, which yielded two seminal publications: de Polignac (1984) for the landscape of Greek cult and Berard et al. (1984) for iconography. The journal *Hephaistos*, established in Hamburg in 1979, is as devoted to theoretical as it is to empirical studies; the journal *Annali di Archeologia e Storia Antica*, published in Naples, offers a range of classical archaeological studies positioned in a contemporary theoretical context (Whitley 2001: 54–56).

New Directions

Survey techniques, perspectives from neuroscience, and the exploration of network models are three areas in which new directions in Greek archaeology intersect with the study of cult. Field surveys have revealed previously unidentified shrines, are a natural format for the integration of ethnoarchaeological techniques, and are critical archaeological components in the growing interests in the intersection of religion, landscape, and geography (Lolos 2005). This "spatial turn" can be traced to the work of Lefebvre and Soja and offers the potential to bridge current research frameworks with ancient geographers such as Strabo (Knott 2005; Kong 2001; Blake 2004; Stump 2008; Tweed 2011). Cognitive and neuroscience perspectives have been brought to a range of topics in Greek religion, including sacred space, vase paintings, and mystery religions: the interest suggests a lessening of the divide from prehistoric archaeologies, where they have had a longer discussion (Martin 2006; McCauley and Lawson 2007; Whitley 2008; Ustinova 2009; Geertz 2010; Schauer 2012). Network models are impacting models of Greek religion, applied to interactions in the islands (Constantakopoulou 2007), the study of hero and

other cult in connecting scattered communities in the Archaic period (Malkin 2011), and the intersection of commercial and religious functions (Gabrielsen 2007; Stavrianopoulou 2006).

Introduction

Roman scholars during the Late Republic and Empire credited Etruscan religion with much that was basic to Roman cult and ritual, most notably the "scriptures" of the *etrusca disciplina*, which they believed had been committed to writing in the earliest days of the cities of Etruria. Even though Etruscan culture, like its language, was perceived as radically different from that of the rest of Italy, as early as the Iron Age (and probably before), many sacred places, rituals, and material aspects of religion were shared with the Indo-European, Italic tribes; by the fourth century BCE, the neighboring Faliscans overtly shared sanctuaries (e.g., Lucus Feroniae) and utilized Etruscan art and script for religious depictions and votive dedications. The strong bonds to Etruscan cult were retained even after the Christianization of the empire: pagans exploited the Etruscan scriptures as a foil to Judaeo-Christian revelation, and in 410 CE, Etruscan haruspices offered to summon thunderbolts to defend the city of Rome from Alaric's army.

Religion in Italy was constantly evolving, in tandem with the growing complexity of societies, in response to catastrophes and through exposure to alien cultures. While sacred places and basic attitudes of worship, divination, and expiation were maintained over many centuries, such familiar (to us) features as temples and cult statues were optional or mutable in Italic and Etruscan practice. By the mid-third century BCE, Rome dominated Etruria, the Italic tribes, and Greek southern Italy; Sicily was soon to follow: almost immediately artistic and ritual aspects of many cults began the process of syncretism, interpreted by some scholars as a means of "Romanizing" or achieving favor within the new political system. During the last two centuries of the Republic and the first two of empire (second century BCE – second century CE), conquests abroad would escalate the process through the adoption of foreign cults. Worship of Cybele (Magna Mater/Great Mother) from Asia Minor and Aesculapius (imported from Kos in a time of plague) came in response to state initiatives and consultation of Greek oracles. The cults of Dionysos/Bacchus, Isis, Mithras, etc., begun as popular, sometimes underground, movements were at times suppressed but ultimately embraced by all levels of an increasingly diverse population. Rome developed new cults to commemorate abstract principles such as piety, honor, and hope, quite different from the cults and myths of the chthonic or Olympian gods. As early as the death of Julius Caesar, an imperial cult began to form, asserting the special status of members of the emperor's family and enhancing respect for the imperial regime. The acceptance of Christianity by Constantine in 303 CE was the next, and revolutionary, stage in the process.

Although references to primitive religion appear in the Classical authors and we know that scriptures existed and were consulted, the actual matter of Italo-Roman cults can today only be restored by reference to archaeological evidence. Scholarly interpretations may be skewed by the situation of Roman dominance of Italy and by the failure of Roman priestly colleges to preserve intact the writings of earlier groups. Numerous references to the *etrusca disciplina* and epigraphic finds such as the *Iguvine Tables* (from Gubbio, Italy) attest to such lost documents. The texts themselves may only be reconstituted from references left by Roman authors who wrote centuries after the various scriptures had been revealed or posted: so all such analyses must be appraised with caution. (Main authors: Livy; Cicero, *De divinatione*; Ovid, *Fasti* and *Metamorphoses*; Seneca, *Naturales Quaestiones*; John the Lydian, *De ostentis*; Martianus Capella, *De nuptiis Mercurii et Philologiae*; Censorinus, *De die natali*; Macrobius, *Saturnalia*.)

Historical Background

Pre- and Protohistoric Evidence

Ever since the Neolithic period, burials attest to funerary religious cult, in the placing of offerings with the prepared dead; the evidence culminates in the dramatic change (perhaps inspired by a cult or religious revival?) in the Final Bronze Age (c. 1200–1000 BCE) to highly formalized cremation ritual and the use of biconical urns, sometimes dressed or decorated with clothing or ornaments. In Latium, some cremations were buried in hut-shaped urns with miniature sets of vessels and even figurines placed inside: surely tokens of ancestor cult. Other Iron Age finds, especially certain metal hoards buried on the outskirts of hut villages, may represent boundary offerings, and images used to decorate vessels and metalwork include boats and birds, perhaps recalling the sun-barque or messengers of the gods. At Etruscan Tarquinia (Pian di Civita) burnt sacrifices and animal bones and antlers mark a sacred area of the ninth through sixth centuries BCE (below).

Key Issues/Current Debates

The Primacy of Writing

Written religious documents included the Etruscan received scriptures, the *etrusca disciplina*, believed to have been dictated by the prophet Tages, a supernatural being resembling a child with the features (teeth, gray hair) and wisdom of an old man (*puer senex*). He emerged from a plowed furrow made by Tarchon, founder of the city of Tarquinia, and proceeded to sing or recite the directives of the gods on divination and required ritual. At the end of his mission, he disappeared back into the earth. The verses included the doctrine of *saecula*, time cycles allotted to different humans and cultures, including Rome, the doctrines on boundaries and land (some preserved by the Roman surveyors' guild: the "Prophecy of Vegoia"), and the *libri Acherontici*, texts covering funerary ritual. Some terms incorporated in Etruscan and Italic cults are preserved in glosses by later authors, e.g., *aiser*, Etruscan for "gods," and *camillus* for a youth officiating in certain cults.

The *etrusca disciplina* was not the only recorded/received scripture in Italian culture: the Latin verse "Prophecies of Marcius" was attributed to an illustrious wandering prophet of legendary times and was circulating in Latin literature by the third century BCE (Livy 25.12.2–15). The Sibylline books, also of foreign origin (the sibyl who sold them to King Tarquinius was said to be from the oracle of Apollo at the Greek colony of Cumae), were kept secret at sacred locations in Rome and consulted in times of crisis, at the order of the Senate. Such texts suffered precarious fortunes, being transferred to different temples and archives in times of fire or war and occasionally having to be reconstructed from dispersed copies.

The Umbrians of Iguvium (Gubbio) displayed, on seven large bronze plaques, the "*Iguvine Tables*," inscribed in Umbrian language using either Etruscan or Latin script. Discovered in 1444, they were written during the third to first centuries BCE as transcriptions of much older documents directing animal sacrifices, observation of birds (augury), and purification rituals

linked to Jupiter Grabovius (and other gods). The faithful of Samnium recorded in the *Agnone Tablet* (now in the British Museum) the mystery cult of Kerres (Ceres/Demeter), using the Oscan language of the Bay of Naples.

Rome itself posted the *Laws of the Twelve Tables* and other laws believed to have been created by the pious, early seventh-century BCE king, Numa Pompilius: such laws as the *lex regia de mortuo inferendo*, still attributed to Numa in the era of Justinian (d. 565 CE) (*Digesta 11.8.2 Marcellus 28 dig.)*, instilled a connotation of cosmic, religious significance into some state regulations.

Divination

Religion throughout Italy seems to have embraced a wide array of divination techniques and rituals, many of them credited to Etruria by the Romans. Augury (the study of the flight of birds, clouds, lightning, and thunder), haruspicy (examining the organs, especially liver, of a sacrificial victim), and the study of *prodigia* (unnatural phenomena and creatures) may all be traced to the *etrusca disciplina*; sacrifice and bird augury appear in the *Iguvine Tables* and in the Latin tales of Romulus and the founding of Rome. The bronze "Piacenza Liver" model, inscribed with the names of Etruscan gods on compartments corresponding to the regions of the universe, is believed to have been a symbolic or educational tool for haruspices; some elements of the procedure and terms can be traced to much older, Mesopotamian haruspical models and texts.

The philosopher Seneca (d. CE 40) (*Naturales Quaestiones* 2.32.2) commented on Romans' perception of the Etruscan scriptures and rituals: "This is the difference between us and the Etruscans, with whom resides the utmost learning for interpreting lightning: We believe that lightning is caused by clouds colliding, whereas they believe that clouds collide in order to create lightning. Since they attribute everything to the divine, they are led to believe not that events have a meaning because they have happened, but that they happen in order to express a meaning."

The Umbrian *Iguvine Tables* also contain directives on divination, while under Rome, the College of 60 Haruspices (*Ordo LX Haruspicum*) operated under the Roman state, presumably following a long Etruscan tradition; it was based at Tarquinia. Eventually, official haruspices traveled with Roman armies and practiced in most regions of the Empire. From early times, oracular shrines were maintained, the most famous perhaps that of Fortuna Primigenia at Praeneste, which included caves and an elaborate, multitiered sanctuary inspired by the great Hellenistic Greek shrines but constructed in concrete and other Roman building materials: modern Palestrina conforms to the outline of its second century BCE plan.

Rituals

When divine messages warned of the need for expiation, the books were again consulted for the rituals by which to make amends to the gods (in Rome this included lustration, when the whole city participated in processions, sacrifices, and rededication). Other ceremonies, again attributed to Etruria, site of the peninsula's first cities, were the essential rites by which cities are founded (presumably the source of Romulus' plowing of a furrow with bull and cow to delineate the city's sacred boundaries). Such a furrow may have been identified in seventh-century levels at Etruscan Veii. Other rituals involved processions and displays such as the chants and leaping dances of the Arval Brethren and the carrying of gods' statues in processions. Many rituals surrounded liminal events such as birth, marriage, and death. The Roman state held regularly scheduled rituals of *vota* – vows made by consuls and priestly colleges with special reference to wars, battles, and catastrophes such as epidemics; generals might vow to build a temple with future spoils.

Little is preserved of such personal rites as prayers, but comments in the ancient authors show that such communications had to be accurately recited and must be repeated in entirety if the speaker stammered. Vows must be made and resolved publicly, with promised, meaningful offerings: inscriptions on vases, cult equipment, statues, and personal belongings offered in fulfillment of vows sometimes give the names of the grateful (in Etruria occasionally including freedmen or their families). In Latin custom, votives

often were marked *v.s.* for *votum solvit* ("she/he fulfilled the vow"). Again, in votive religion, writing assumed a significant position in the conduct of religious activities. On analogy to modern Christian customs of offering inscribed representations of objects desired and gained or body parts healed, these represent phenomena already granted to the worshipers by the gods. A significant change in society and belief around the end of the fourth century BCE seems to be illustrated by the rapidly spreading phenomenon of offering anatomical votive models (usually terracotta, but in the Archaic north of Italy, in metal). These take the form of rationalized internal and external organs, heads or complete statues, and figures of swaddled infants; large numbers of uterus models were found in such cults as those of Vei/Demeter, Uni/Hera, and Turan/Aphrodite at Gravisca, an extramural sanctuary of the Tarquinian port. After c. 300 BCE, there is evidence of freedmen participating publicly, as well as large numbers of women, and similar votive models and inscriptions occur in Latin and Campanian shrines also, where even in healing cults, almost any god might be the recipient/patron, including Minerva and Hercules.

Other ritual activities indispensible to Etruscan and Italic cults include sacrifice, usually of animals, often of inanimate foodstuffs. Possible human sacrifice is suggested in rare evidence such as a wounded warrior's skeleton buried anomalously in the sacred area of Tarquinia's Pian di Civita in the mid-eighth century BCE: he had been killed by an axe blow similar to that used for ritual slaughter of sheep or cattle. Rare scenes depicting Etruscan funerals with a costumed character, "Phersu," seem to show blood sacrifice (a wounded, captive performer) but are the only potential evidence of atavism of earlier human sacrifice. The Roman sacrifice of enemy couples (Gauls and Greeks) buried alive in the Forum Boarium (228, 216 BCE, Livy 22.57.6) was considered a response to state crises, rarely repeated and by Pliny's day prohibited (*Natural History* 28.12ff.). Traces of young animals cremated with the deceased at Etruscan funerals (Iron Age through Hellenistic period) may illustrate the practice of creating the *dii animales* which Roman authors attributed to Etruscan scriptures: for the recently dead to metamorphose into "spirit gods"(from Latin *anima*), a sacrifice of living blood was required. The bloody mythological scenes (battle, murder, monsters) often depicted on Etruscan urns and sarcophagi may be tangible reminders of these beliefs.

Many details are known, from art and literature, of Roman ceremonies: Roman men covered their heads, if not with the special priestly headgear, like the *apex* or *galerus*, then with a fold of the toga; many votive heads and statues depict this pose *capite velato* ("with veiled head"). Although they may be found in the same votive deposits (as at Ponte di Nona outside Rome), comparable (male) images lacking the veiled aspect are often considered to represent Etruscan rather than Italic practice. Rome maintained a plethora of religious colleges, cults, and offices, all perceived as in some way aiding the state as a whole. Such offices as the *pontifex maximus*, who determined dates of festivals and law courts, the *flamines* (priests assigned to specific state cults in Rome and the towns), and Vestal Virgins were strictly controlled with harsh penalties for impropriety; priests' wives, too, came under such restrictions. Aristocrats assumed the priestly offices, and many apparently served in multiple cults, to judge from the Etruscan *curriculum vitae* held (as a scroll) in the hand of the effigy of Lars Pulenas, on his sarcophagus (c. 270 BCE). *Netsvis* and *cepen* are read as Etruscan titles for priests, the former indicating a haruspex, to judge from the bilingual epitaph of Lars Cafates/Cafatius, found at Pesaro: he was *netsvis trutnut* and *frontac* – in Latin, *haruspex [et] fulguriator* ("priest of divination by liver and by lightning"). Rome had many religious colleges, staffed mainly by the upper classes, although some allowed freedmen full membership, and certain cults, such as that of Isis, welcomed slaves also.

The Roman year was filled with festivals (*feriae*) of particular cults and state ceremonies, including many celebrations of the agricultural year, the flocks, and historical events; they usually involved a sacrifice and distribution of the meat,

followed by games. For instance, the Megalesia included theatrical performances and games honoring Magna Mater, introduced from Asia Minor in the third century BCE (early April). Festivals include Vinalia (April 23 and August 19, wine), Robigalia (April 25, to prevent rust on grain), Consualia (August 21, storage of crops after harvest), Saturnalia (December 17, end of year), and Lupercalia (February 15, purification and fertility of flocks). Later many dates accrued for the anniversaries of temples or cults founded, historical events, imperial birthdays, etc.

Sacred Places and Structures

Places of worship did not require a formal structure and often focused on some special natural feature, with worship conducted in the open air; there is ample evidence across the Italian archipelago for the use of caves as cult places, from the Neolithic through the Iron Age and beyond. Most sacred sites show cult activity in later periods as well. Etruscan cult places included the seashore (Gravisca, Pyrgi, Punta della Vipera), swamps, springs, or lakes (Brolio, Falterona) and mountaintops (Lucus Feroniae, shrine of a Sabine earth goddess, shared with Faliscans). Confederated sanctuaries were often politicized, such as the *Fanum Voltumnae apud Volsinios* (the shrine of Voltumna/Vertumnus in the territory of Volsinii, i.e., Orvieto), where an extramural sanctuary has been identified, with subsequent structures (Christian church) as late as the medieval period. The Latin League celebrated annual festivals in April on the Alban Mount with the sacrifice of a white heifer and communal meal.

One of the most famous cults, both Etruscan and Italic, was that of Soranus (oracular, syncretized to Apollo Soranus) on Mount Soracte. A sanctuary of the goddess Mefitis at Ampsanctus in the Hirpine territory centered around a sulfurous spring. At Rossano di Vaglio in Lucania, the extra-urban cult of Mefitis included a paved courtyard with sacrificial altar; it also featured the worship of the Oscan war-god Mamers (c. 350 BCE to first century BCE or CE). Many modern scholars, following ancient authors in emphasizing the primitive aspects of Italic, supposedly tribal, culture, have undervalued the sanctuaries and monuments of such cultures as the Samnites. Their great rural sanctuary at Pietrabbondante included a temple and theater complex probably used for political and military gatherings which included bull sacrifice and offerings of weapons. Like the Republican-era rural shrine at San Giovanni in Galdo (a *sacellum*, a small shrine, within a rectangular precinct), such sacred places served to reinforce the boundaries of different territories. The Italic cults often favored Hercules or patron goddesses such as Juno of Gabii, whose Republican-era temple still stands. To the south, Lucania has also yielded evidence of crossroad sanctuaries and cults within the households of Italic aristocrats. Pompeian murals (Boscotrecase, House of Agrippa Postumus) illustrate such idyllic rustic shrines and country worship.

The phenomenon of "visiting gods," well known in Greek sanctuaries, was also frequent in Italic cults. At Iguvium, the great bronze plaques cite at least 29 deities, to be honored with rituals such as auspices and sacrifices conducted at the city gates. These were undertaken on behalf of the community in general or the college of the "Brotherhood of the Atiedii" (paralleled at Rome by the Arval Brethren worshipping Dea Dia, or the Salii, the "leaping priests" of Mars).

At Samnite Pietrabbondante, the outdoor shrine only acquired a temple building between the end of the third century and 90 BCE (the period between the Hannibalic War and the Social War). By that time, generals in the midst of military campaigns or battles might vow to build a temple if their patron god(dess) gave victory: in Rome, the temples of Mater Matuta and Fortuna Virilis in the Forum Boarium (now beneath the church of Sant'Omobono) were dedicated by the victorious Camillus (replacing a sanctuary of the regal period), and the small, jewel-like, Republican temples placed close together along the triumphal route (now Largo Argentina) seem to be similar victory monuments (one dedicated to *Fortuna Huiusce Diei*, "Good Fortune on This Day"). The triumph (a tradition also attributed to Etruria) was essentially a religious ceremony for a

victorious general and his army, a procession exhibiting spoils and captives, culminating in a sacrifice at the Capitoline Temple and slaughter of prisoners (as of Vercingetorix after Caesar's triumph in 50 BCE).

The earliest formal temple seems to be a small *sacellum*, a simple, rectangular shrine erected c. 600 BCE in the city of Veii; at port towns such as Gravisca and Pyrgi, Greek residents influenced the building of cult rooms and eventually an early peripteral temple at Pyrgi (Temple B, sixth century), although it was constructed with Etruscan-style terracotta roofing and ornamentation. Pyrgi had a motel-like building possibly for ritual banquets (erroneously associated with "sacred prostitution"), and Temple A, erected c. 460 BCE, was a large Tuscan-style temple with dramatic, narrative terracotta sculpture covering the ridge and other beams in an insert roof. The famous *Pyrgi Plaques*, gold inscriptions nailed to some structure and given ritual burial when the temples were deconsecrated, were inscribed c. 500 BCE to commemorate an event in the reign of "king" Thefarie Velianas of Caere – one is in the Punic/Phoenician language and script and the other two in Etruscan.

At Veii, the famous extramural temple crowned with terracotta statues of Apollo and other gods was built late in the sixth century BCE and included a precinct with a large ritual pool, altar, and other structures. (It was not dedicated to Aplu/Apollo, but probably to one or more goddesses.) Large quantities of votive offerings once displayed there were found buried on the site, including gifts of Aulus Vibenna and members of the once-royal Tolumnii family.

In Latin terminology, *templum* was originally simply a place for public activity, approved by Jupiter, inaugurated when *augurs* (divination priests) consulted the gods by taking auspices in various ways; this activity had to occur inside the ritual city boundary, the *pomerium*, within which burial and armed soldiers were banned. (Inscribed stone *cippi* found at Daunian Bantia (modern Banzi, Italy) may have marked an *auguraculum*, a space designated for taking auspices for this Roman colony.) Crucial for an Etruscan or Italic sanctuary were an altar and precinct wall; altars of different types reflect the character of the cult, such as the *mundus* altar, which had a drain into the earth, for chthonic and underworld gods. The so-called Tuscan temple, a rectangular building on high podium, with deep, colonnaded frontal porch, broad eaves, and ornately decorated, insert roof, was never rigidly canonical in proportion or plan, but can be seen in the remains of terracotta roofing systems and large plans at Etruscan and Latin sites such as Veii, Vulci, Tarquinia, Caere, Satricum, and Velletri. The tripartite cella became characteristic of the Capitolium, the main temple of the Roman state, duplicated in many municipalities as Rome grew; rooms were linked to Jupiter, Juno, and Minerva. By the Late Republican period and Empire, Roman temples were hybrids of "Tuscan" and (Hellenistic) Greek design.

Shrines could also be erected in necropoleis, such as the Cannicella Necropolis at Volsinii/Orvieto, where running water and a nude goddess statue were displayed, along with votives. In the center of the necropolis of Sovana, there was even a healing cult, where anatomical votive models (of the viscera) were dedicated. Several sanctuaries employed running water features, including the fifth-century fountain shrine at the Adriatic colony of Marzabotto. During the period of Roman colonization of Etruria, worship also continued within the ruins of some cult places, where masses of votives were left in nighttime rituals at Gravisca and at Veii Latin names appear on the offerings.

It was assumed (by ancient and modern authors) that when the monarchy ended, the king's priestly functions were delegated to citizens, resulting in a number of fragmented offices such as the so-called *rex sacrorum* ("king of sacred things"). In Rome, the Regia, supposedly the royal palace converted to the headquarters of the state cult (of Jupiter, Juno, and Mars), was situated in the heart of the Forum near the House of the Vestals and ultimately became the office of the *pontifex maximus*. (Which office was exploited by Julius Caesar among others; certainly politicians took advantage of the opportunities of public religious office, as would the emperors).

Domestic Cults

Little evidence has been detected for permanent structures of household cult in Etruria – although much information has been attributed to the ancestor cult practiced in funerary ritual: some tombs encompass cult rooms fitted with carved furniture as if the family expected to picnic with the deceased occupants of the tomb; statues of venerable personages, enthroned and with footstools, even scepters, in the Tombs of the Statues and of the Five Statues in the territory of Caere, while showing Near Eastern/Syrian inspiration in their design and carving, appear to be monumental versions of such earlier figures as the clay humanoids found in some Latin hut urns or the seated banqueter on the lid of a Volterran Iron Age cremation urn from Montescudaio. The deceased are presumably now ancestors; Etruscan tombs of the fourth century depict a family's earlier generation at banquet in the underworld, enjoying the attention of Hades and Persephone. Images of Vanth, the Etruscan death goddess, show her as beautiful and nubile, sometimes winged, or scantily clad, and other funerary images emphasize sexual aspects of death: ancestors are intrinsically bound with the ongoing fertility of their family.

Strong traditions of funerary ceremonies are found in all cultures of ancient Italy, including artistic or other references to the journey to the afterlife, completion of the course of life (symbolized by steering oars or ships), apotropaic scenes, offerings and consumption of a meal with the dead, funeral games, and the equation of sex and death. Roman funerals displayed effigies, even masks of deceased illustrious family members. The Roman festivals of Lemuria and Parentalia were held in May and February in honor of the spirits of dead members of the Roman household, the former hostile spirits, and the latter benign members of the immediate family.

Roman literature preserves commentary on Italic household and family cults including the Lares and Penates, guardian spirits for the Roman household; Lares may derive from the family land, while Penates protected the larder. The houses destroyed at Pompeii and Herculaneum in 79 CE contain several Lararia, cabinet-like shrines imitating a temple, with paintings and/or figurines depicting dancing Lares (youths with cornucopiae) and venerable bearded snakes, with the occasional offering bowl. The Roman practice of a free-born youth dedicating his golden *bulla* (a "bubble" amulet in essence like a native American medicine bag) in the shrine of the family Lares was preceded in the Iron Age by Picene, Etruscan, and Faliscan wearers of similar, hollow lockets.

Magic, although the dark side of belief, was a prominent feature of ancient Italy, as seen in curses and binding spells, often worked in necropoleis, as in a pair of inscribed lead, nude and bound figurines depicting an Etruscan man and woman, found in a tomb in Sovana. During the Roman Empire, binding spells were often recorded on lead tablets (*defixiones*) and deposited in secret in the circus or court with pleas to underworld gods to affect the outcome of competitions and trials.

Renfrew, Colin

Neil Brodie
Scottish Centre for Crime and Justice Research, University of Glasgow, Glasgow, UK

Basic Biographical Information

Colin Renfrew (Lord Renfrew of Kaimsthorn) is best known in archaeological circles for his contributions to archaeological theory. He is rather less well known for his work toward protecting cultural heritage, which he has often performed away from professional and public view. He has served in various capacities on the Hampshire Archaeological Committee (1974–1981), the Royal Commission on Historical Monuments (England) (1984–1986), the Historic Buildings and Monuments Commission of England (1984–1986), the UK National Committee for UNESCO (1984–1986), and the British School at Athens (2004–2010). Since the 1990s, he has been an outspoken critic of the illicit antiquities trade and its promotion of archaeological looting (Renfrew 2000, 2003, 2006; Brodie et al. 2001; Brodie and Renfrew 2005).

Major Accomplishments

In 1991, Renfrew became the first director of the newly established McDonald Institute for Archaeological Research at the University of Cambridge, and in 1997, he established as a project of the McDonald Institute the Illicit Antiquities Research Centre (IARC). Staffed by Neil Brodie and Jenny Doole, with the association of Peter Watson, the mission of the IARC and its newsletter *Culture Without Context* was to research and raise awareness of the damage caused to cultural heritage by the antiquities trade and to promote appropriate public and professional policy responses. In recognition of its work, the IARC was awarded the European Archaeological

Heritage Prize (2004) and the Archaeological Institute of America's Outstanding Public Service Award (2006). In 2004, Renfrew retired as director of the McDonald Institute, and in 2007, the IARC was closed down.

While fully involved with the work of the IARC, Renfrew continued his committee work and was active in promoting ethical and legislative change aimed at regulating the antiquities trade. As a trustee of the British Museum (1991–2001), he was instrumental in drafting a new (1998) acquisitions policy, which stated that in future the museum would only acquire an antiquity when there was documentation to show that it had already been out of its country of origin by 1970, the date of the UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership on Cultural Property, or legally exported since that date (Renfrew 2000: 124–125). Also in 1998, he encouraged the Council of the British Academy to adopt a similar policy to guide scholarly engagement with traded antiquities (Renfrew 2000: 126–128), and likewise the UK's National Art Collections Fund after he was appointed to its executive committee in 2001. The "bright line" of 1970, initially taken up in 1970 by the Museum of the University of Pennsylvania, has since been adopted by other museums, including the J. Paul Getty Museum (2006) and, acting with Renfrew's advice, the Badisches Landesmuseum in Karlsruhe (Renfrew 2006: 251–255). It is largely through Renfrew's advocacy that the 1970 threshold has now become an international standard, recommended by the UK government in 2005 and by the Association of Art Museum Directors in 2008.

Renfrew was created a life peer in 1991 and since then he has been prepared to use his position in the House of Lords to question the UK government about policy (*inter alia*, the failure of the US-UK coalition to prevent the looting of the Iraq National Museum in 2003 (Renfrew 2003)) and to scrutinize some of the less than transparent out-of-court maneuverings of rich and powerful collectors, such as those involving Lord Northampton and the Sevso Treasure (Renfrew 2000: 46–51) and Martin Schøyen and the Aramaic incantation bowls (Balter 2007). He has not shrunk from exploiting his celebrity to raise issues in the press, using the occasion of his attendance in Paris for the 30th anniversary celebrations of the 1970 UNESCO Convention, for example, to question publicly the acquisition by the Louvre of some Nigerian Nok terracottas (Riding 2000). In 2009, for his work in opposing the illicit antiquities trade, he was awarded the SAFE Beacon Award.

In 2000, Renfrew was invited to be a member of the ministerial Advisory Panel on Illicit Trade (ITAP), convened by the UK government to advise on policy as regards the antiquities trade. Recommendations made in ITAP's report that the UK should accede to the 1970 UNESCO Convention and introduce specific criminal legislation were subsequently realized, with accession to the UNESCO Convention in 2001 and enactment of the Dealing in Cultural Objects (Offences) Act in 2003.

Repatriation Acts: Before NAGPRA

Larry J. Zimmerman
Indiana University-Purdue University Indianapolis/Eiteljorg Museum, Indianapolis, IN, USA

Introduction

As influential as it has been on archaeology, museums, and Indigenous people – well beyond US national borders – many people consider the enactment of the Native American Graves Protection and Repatriation Act (NAGPRA) of 1990 in the United States to be the beginning of the repatriation movement. But in the US, repatriations and reburials of human remains, as well as return of sacred objects, started substantially earlier. Even before repatriation and reburial became openly controversial, archaeologist Roderick Sprague and anthropologist Deward Walker, for example, had worked closely with Nez Perce people in the state of Idaho, quietly repatriating remains as early as the late 1960s. As the issues became heated over the next two decades, American Indian demands and attempts by the archaeological and museum communities to respond eventually led to NAGPRA. Before NAGPRA became law, however, Indians and archaeologists had numerous discussions and occasionally bitter arguments about respectful treatment of the dead. As the issue developed, there were efforts to compromise, several repatriations occurred, and many states enacted repatriation laws (Price 1991). The path to NAGPRA was complex and meandering.

Tribes had expressed concerns about the treatment of their ancestral remains for decades but had little power to stop excavations and collections of skeletal remains by the scientific community and museums (Thomas 2000: 52–63). Intense pressure for archaeologists to stop excavating human remains, however, accompanied the intensifying American Indian activism of the late 1960s, which was linked in part to the general social upheavals of the time in the United States. As they found their voice, one activist group, the American Indian Movement (AIM), specifically targeted archaeology in their agenda for change. In 1969, the Onondaga (Iroquois) fought for the return of *wampum* belts from the New York State Museum, and in 1971, AIM disrupted an excavation near Welch, Minnesota. That same year, activists occupied the Southwest Museum in Los Angeles, requested repatriation of human remains and sacred objects, and demanded that other objects be taken off display. In 1972, AIM members confiscated human remains from Colorado State University. In the aftermath of the Wounded Knee II takeover in 1973, the federal legal system distracted the AIM leadership from addressing issues such as Indian concerns about archaeology at the national level (Deloria 1973: 29–35), so not until the late 1970s and early 1980s did AIM again specifically demand ethical treatment of human remains and grave goods by archaeologists and museums. However, pressure continued to grow at the state level, and one of the key pre-NAGPRA events arose in the state of Iowa.

In 1971, archaeologists removed Indian remains from the edge of a pioneer-period 1860s cemetery in southwest Iowa that was being disturbed by highway construction, taking them to an archaeology laboratory to be studied; the numerous non-Indian remains were immediately reburied in a nearby cemetery. *Ihanktonwan* (Yankton Sioux) activist Maria Pearson demanded equal treatment of the dead from the governor of the state, leading to the dismissal of the seated state archaeologist and eventually to the passage in 1976 of the first state reburial law. The Iowa law became precedent-setting for other states, structuring a collaborative model for the ethical treatment of human remains. To assure

equal treatment under the state laws, all human remains deemed to be from 150 years ago or older (roughly the time of the first substantial presence of non-Indians in the region) became the responsibility of the Office of the State Archaeologist (OSA), with more recent remains handled by county and state law enforcement officials. The OSA was to arrange for an "autopsy" by a forensic physical anthropologist, essentially an assessment of key skeletal metrics and examination for gross skeletal pathologies. The remains then were to be returned to genetically or culturally affiliated tribes if identity could be established, but because numerous Indian nations had once lived in the state, affiliation often could not be confirmed. Such "unidentifiable" remains were then reburied in one of four secure, state-owned cemeteries, as close as possible to where the remains were found. All activities were done with the agreement and oversight of the Iowa Indian Advisory Committee and affiliated tribes. The key element in the success of the law proved to be the trust relationship built between the archaeological and Native American communities. The process proved so successful that the state was given an exemption from the processes of NAGPRA when it was enacted 14 years later. Other states copied many elements of the Iowa statute, and some core elements of NAGPRA stem from it.

The Iowa precedent provided impetus for repatriations in other places. Most involved small numbers of remains, but one large repatriation and reburial drew national attention, especially in the archaeological community. The 1978 excavation of nearly 500 individuals from the Crow Creek site in central South Dakota required collaboration between archaeologists, Native Americans, and a federal agency. Archaeologists and the US Army Corps of Engineers (COE) became involved when erosion and looting disturbed the remains. Because the individuals died in a fourteenth-century massacre and represented a large group of people dying at the same time, they represented an almost unique population for anthropological study. At the same time, because the remains were discovered on the Crow Creek Sioux (Lakota) Reservation, the local residents demanded that the archaeologists and the COE hear their concerns about how the remains should be treated and what should eventually happen to the skeletons. The Lakota would let the project proceed only when the archaeologists and the COE agreed that the remains would not leave the state and would be reburied after study (Alex and Zimmerman 1981). In 1981, the remains were reburied near where they were discovered. The project caused many members of the archaeological community to speak out against repatriation and reburial, but Crow Creek was one element among many that made archaeologists pay close attention to Indian demands.

At about the same time, AIM and the International Indian Treaty Council established American Indians Against Desecration (AIAD), directed by Jan Hammil, an urban Indian woman with Mescalero Apache heritage. Hammil pressured organizations such as the Society for American Archaeology (SAA) to listen to Indian demands for repatriation. In 1982, when the SAA Executive Committee determined that the organization should pass a resolution against reburial, Hammil and a small delegation of AIM members met with the committee to convince them not to adopt the resolution (Zimmerman 1989). As a result of events at that meeting, the SAA waited until the following year to do so and without consultation, much to the chagrin of AIAD. Although the SAA appeared to be against repatriation, many archaeologists sought to understand Indian concerns and some continued to work toward some compromises. Continuing demands by Indian people pushed several local, regional, and national organizations, eventually including the SAA, to sponsor meetings and conference sessions during which Indians and members of the archaeological community could present their views. The media, supported by some archaeologists and Indians, generally portrayed the issues as bipolar – Indians versus archaeologists and religion versus science – but there was actually a continuum of opinion about repatriation and reburial. In 1986, Hammil and a number of other Indian people joined Indigenous people from around the world at the first World Archaeological Congress (WAC) meeting in the UK, where they exchanged views

about repatriation in their regions. Archaeologists who attended the meeting were generally supportive of repatriation, and the WAC leadership urged Hammil to organize an international conference on the topic, which was held at the University of South Dakota in 1989 as a WAC Inter-Congress on Archaeological Ethics and the Treatment of the Dead. That conference resulted in the Vermillion Accord, which became the basis for similar statements in Canada and Australia, and was the first time Indigenous people and archaeologists were able to come to agreement on working toward real solutions about reburial internationally. As with the enactment of the Iowa law and the Crow Creek reburial, however, most disputes about repatriation – there were many – occurred at the local or regional level, but they certainly influenced the national scene. All were important to the people directly involved, but a few had a very direct impact on the development of NAGPRA.

For more than a decade, the people of the Omaha nation had sought the return of many sacred objects from Harvard University's Peabody Museum, but especially the return of *Umon'hon'ti*, their sacred pole. In 1888, tribal members were under extreme pressure to abandon their traditional beliefs and accept Christianity. To safeguard *Umon'hon'ti* and other sacred objects, including ceremonial war pipes and their sacred shell, the tribe had turned them over to ethnographer Alice Fletcher who transferred them to the Peabody. After an extraordinary effort to reclaim their objects, the Omaha received the sacred pole in 1989, and the Peabody has since returned other sacred objects (Ridington and Hastings 1997). Although other museums had repatriated sacred objects before the Peabody Museum did, the museum's stature was symbolically important for other museums, making them very aware that Indian concerns involved more than just human remains.

Two related repatriations of human remains were directly relevant to NAGPRA because of the involvement of the Native American Rights Fund (NARF) and the Pawnee nation. One of the NARF attorneys for both cases, and a man of Pawnee heritage, was Walter Echo-Hawk, who was one of the key authors of NAGPRA. In 1985, the Kansas State Historical Society sought to acquire and build a museum around the so-called Salina Burial Pit, a tourist attraction outside Salina, Kansas. Open since 1937, the privately owned business displayed the remains of 146 people. They had been buried in the twelfth to thirteenth centuries, and as most archaeologists agree, they were probably direct ancestors of the Pawnee people. When the Pawnee, who now live in the adjacent state of Oklahoma, heard about the plans, they objected and demanded that the facility be closed and their ancestors reburied. Many archaeologists in the region fought closure of the site, but to his credit, the state archaeologist, Tom Witty, agreed to listen and eventually agreed that the site should be closed. In 1989, Kansas enacted an unmarked burials law similar to the Iowa law. Then in 1990, the Pawnee finally shrouded each body with a blanket or shawl and, after prayers and a funeral feast, covered the entire pit with clean sand, topped by a concrete cap to protect the remains from future disturbance (Echo-Hawk and Echo-Hawk 1994).

In 1988, the Nebraska State Historical Society (NSHS) became embroiled in controversy when it refused to honor several requests from Lawrence Goodfox, Jr., on behalf of the Pawnee nation, to return human remains known to be directly ancestral to the Pawnee and grave goods associated with known individuals, long held by the NSHS. When the society director refused to respond to the Pawnee requests, a nationally visible controversy ensued. With NARF's help, the Pawnee joined forces with other regional tribes to ask the Nebraska legislature for help in the form of a state law. After rancorous debate, in 1989, the coalition saw passage of the Unmarked Human Burial Sites and Skeletal Remains Protection Act, which required Nebraska public museums to return all tribally identifiable skeletal remains and burial offerings to tribes that requested them for reburial.

What is important about these repatriations is they directly set the stage for NAGPRA. National publicity had an impact on the US Congress, and elements of the Nebraska law found their way directly into NAGPRA because Walter Echo-Hawk helped author both laws. While these local disputes and repatriations were underway, Indian people continued to press the US Congress to work toward a national solution. As much as

anything, the Smithsonian Institution, as a federal agency, became a symbolic target because of the large number of remains and objects the Smithsonian housed. After negotiations between Native American groups, the American Association of Museums, the SAA, and others, Congress was willing to pass the National Museum of the American Indian (NMAI) Act of 1989, which 15 years later saw the opening of the NMAI as part of the Smithsonian but also set up a process for repatriation of human remains and grave goods in the Smithsonian's possession. While there are differences, that process became the model for NAGPRA, which was signed into law the next year, but only after intense negotiations and compromises (McKeown 2013).

There are very likely differing assessments of the importance of certain individuals or events leading to a national repatriation law in the US, but NAGPRA stemmed from the many local acts of repatriation that happened from the 1960s until NAPGRA became law in 1990. Many people were involved in the process, from quiet, resolute tribal elders, holy people, and officials to outspoken activists. Many non-Indian archaeologists, museum professionals, and local, state, and federal government employees worked to resolve difficult issues. As many have said, even though repatriation is driven by national law, it is still mostly a local matter that depends on trust and good will.

Definition

In a general sense, repatriation means returning to your country of origin, but in the specific sense of archaeology, it has meant the return of human remains and any associated objects buried with the dead, as well as sacred objects or other items of cultural patrimony that were inappropriately, illegally, under duress, or otherwise taken without permission from a nation or people. Colonized Indigenous people were often the victims of the removal of such objects. In the process of decolonization during the last half-century or so, they have demanded return of these items. In North America, the situations in which human remains and objects of cultural patrimony were removed from rightful, usually Native American ownership ranged from outright theft to a hope that a stronger authority might better be able to protect objects for the future. Acts of repatriation have sometimes been done willingly or carried out after negotiation, but in many instances, the rightful owners have had to act by force or take legal action to have objects returned to them.

Key Issues/Current Debates/Future Directions/Examples

In the United States, a number of issues have surfaced relating to repatriation, some of them similar to repatriation in other places. Many people, especially with the return of human remains, realized that they had no ceremonies or rituals for the process of *re*burial because no one ever considered that such a ceremony would ever be needed. Thus, many adapted some form of contemporary practice, perhaps with minor variations to account for the age of the remains. As well, many Native American people have been subjected to proselytizing by missionaries and are now Christian. For example, when the Crow Creek Massacre victims were reburied in 1971, there were two traditional Lakota ceremonies, a private ceremony by the Arikara descendants and Catholic, Episcopal, and Baptist Christian rituals.

Another problem in the United States is that many skeletons and burial items have been recovered from what is now considered to be private property. Although some state laws protect all human remains, even on privately held lands, in most cases they do not. Federal law rarely applies to private lands unless the federal government is somehow involved. Private individuals often understand that tribes may want the remains of ancestors returned, but do not know to whom they should give them and often not even precisely where the remains came from, precluding all but a guess of genetic or cultural affiliation. Other private individuals have little concern for the dead and get involved in looting. At the Slack Farm site in the state of Kentucky, looters actually paid a private landowner for rights to "mine" a known precontact Native American cemetery for pottery and other burial objects. Paying no

attention at all to the skeletal material, they dug hole after hole and fragmented numerous skeletons. After protests by both Native Americans and archaeologists, Kentucky passed a burials protection law that encompassed remains found on private land. In spite of such laws, however, there is rarely enforcement and only relatively light sanctions.

Finally, a number of archaeologists and museum professionals still resist repatriation. Commonly heard explanations are that some tribes do not know how to properly care for returned sacred items or perhaps that a particular tribe did not care what happened to bodies after death so should not care if the remains are studied or stored in laboratories or museums. Under NAGPRA, many agencies claimed that remains could not be positively identified as to which tribe was affiliated or that multiple tribes might be, so they did not want to return remains fearing legal action if they were returned to the wrong tribe. Although some of these concerns may be legitimate, many have primarily used them as excuses not to repatriate remains and objects.

Generally, the public understands the concerns of American Indians about the return of ancestors and sacred objects, but many do not, especially when they see the remains or objects as their property or somehow important to collections at their local museum. As for professional archaeologists and museum staff members, NAGPRA has now been in place for more than 20 years, so as new professionals are educated they are taught about repatriation and its importance. Most have an understanding about why NAGPRA came into existence, and even though they might disagree with all or some elements of repatriation, they are now compelled by law to take repatriation into account as part of their regular dealings with Native Americans and other Indigenous peoples.

Repatriation Acts: NAGPRA Repatriation in Tribal Practice

Matthew Liebmann
Department of Anthropology, Harvard University, Cambridge, MA, USA

More than 25 years have passed since the Native American Graves Protection and Repatriation Act (NAGPRA) became law in the United States. According to the National NAGPRA program, this law has resulted in the return of the remains of more than 50,000 individuals, 1.4 million funerary objects, and over 14,000 sacred objects/objects of cultural patrimony to Native American tribes (https://www.nps.gov/nagpra/FAQ/INDEX.HTM#How_many). It has also resulted in the publication of numerous books and articles investigating the myriad issues surrounding the law (Fine-Dare 2002; Killion 2008; Mihesuah 2000; Colwell 2017), including the conditions leading to its passage (Thomas 2000), its legislative background and history (Trope and Echo-Hawk 1992; Lovis et al. 2004), implementation (Anyon and Thornton 2003), and the responses of various stakeholders (Ayau and Tengan 2002; Preucel et al. 2003).

This entry seeks to give insight into the process of repatriation on the tribal side of the law. How does repatriation play out for tribes? How is NAGPRA implemented "behind the buckskin curtain" (Deloria 1995: 1), and What happens to repatriated Native American human remains, funerary objects, and sacred objects after the papers are signed and they leave museum shelves? In what follows, I give some behind-the-scenes insights into the repatriation process at one Native American tribe, the Pueblo of Jemez, where I served as NAGPRA program director from 2003–2005.

For tribes, the process of repatriation often begins with the receipt of an inventory or summary from a museum. This written notice serves to inform the tribe about human remains or objects eligible for repatriation that are currently housed in that museum. *Summaries* are estimates of the number of objects (either funerary, sacred, or those of cultural patrimony) in that museum's collections determined to be culturally affiliated with the tribe in question. *Inventories* are similar but are typically more detailed item-by-item descriptions of human remains and associated funerary objects. Sometimes the tribe is well aware of the locations of these collections prior to receiving a summary or inventory, as is the case with many high-profile sacred artifacts and those collected by well-known expeditions of the nineteenth and twentieth centuries. But in many other cases, tribes are unaware of the whereabouts of collections and sometimes even unaware that such collections exist at all. The practice of sharing and swapping of artifacts and human remains that frequently occurred among museums in the late nineteenth and early twentieth centuries served to break up and scatter collections across multiple institutions, and it is often only with the receipt of an official NAGPRA summary or inventory that tribal officials become aware of their current locations.

At the Pueblo of Jemez, the receipt of an inventory or summary from a museum triggers an established protocol for handling NAGPRA claims. Upon receipt of new summaries or inventories, the NAGPRA program coordinator enters a record of the collections into a computer database created specifically to keep track of NAGPRA claims, along with any accompanying relevant information about the objects or human remains they detail. The information from this database is summarized at regular intervals and presented for review to tribal officials. Over the past decade, this review has been performed either by the Governor of the Pueblo or by a committee of traditional religious leaders appointed by the Governor. This committee, known as the Cultural Resource Advisory Committee (CRAC), comprises 10–15 representatives from the tribe's religious societies who have special expertise in

issues of cultural patrimony. After reviewing the latest inventories and summaries, these tribal officials set the priorities and agenda for future repatriation claims. At Jemez, human remains have typically received the highest priority, followed closely by sacred objects.

Although non-Natives often assume that tribal policies call for claiming everything and everybody deemed eligible for repatriation, this is not necessarily the case. The Pueblos of Santa Clara and Zuni, for example, have declined to repatriate human remains because they have no ceremonies to mitigate the desecration that has occurred to their ancestors (Ferguson et al. 2000:258; Alvin Warren, personal communication 2012). At Jemez, tribal representatives carefully consider each summary and inventory they receive, discussing the pros and cons of repatriation in each case. Issues factoring into their decision include whether or not the items can be appropriately curated once in tribal possession, information that could be gained from returning items to active use, where returned items/human remains will be curated/reburied, whether or not reburial is possible, and future research desires and needs. Furthermore, the tribe does not always concur with the findings of museums. In some cases, museums' determinations of cultural affiliation do not accord with those of the tribe (i.e., the tribe does not consider itself to be culturally affiliated with the items/human remains in question). When this happens, the tribe typically declines to continue the repatriation process. In other cases, the museum may conclude that a tribe is not culturally affiliated, contrary to tribal beliefs. This often results in difficult negotiations and sometimes a hearing before the National NAGPRA review committee.

If an item or collection is judged to be a potential candidate for repatriation, representatives from Jemez usually desire to view the objects/materials (in person if possible) before submitting an official claim. At this stage, the NAGPRA program coordinator typically works with the museum staff to organize a preliminary visit to the museum. Funding for these visits may be covered by the host institution, but more commonly it is paid for out of tribal funds often raised through federal grants administered by the US Department of Interior. Once at the museum, the tribal representatives examine the collections and again discuss the suitability and desirability of repatriation with one another. These discussions are often frank and nuanced as the pros and cons of each repatriation are carefully weighed. On numerous occasions, I have witnessed tribal members peering over an open drawer in a museum storehouse, examining the artifacts within while simultaneously debating whether or not they should be brought home. At times, these discussions acknowledged the irony that those artifacts may not have survived to the present day if they had not been curated in a museum. In some of those cases, the decision was made to postpone repatriation until the day when the tribe possessed appropriate curatorial facilities to properly care for these items in the long term. Following the examination of collections, the tribal representatives commonly meet with museum staff members, who brief them on a proposed timetable for repatriation, any extenuating circumstances, and any likely problems or conflicts. In my experience, these meetings were typically cordial, with both sides working toward an amicable solution; however, in some cases, conflicts can arise, particularly if one side (or even just one person) enters into these negotiations harboring resentments or hostilities.

After the preliminary visitation and viewing of artifacts, the tribal officials who examined the materials eligible for repatriation typically report back to a larger contingent of elders and religious leaders to discuss the Pueblo's wishes and strategies. Based on that conversation, the Governor or CRAC decides whether or not to pursue a repatriation claim. When repatriation is desired, the NAGPRA program director works with the Governor to notify the museum staff of their intention. In theory, the tribe then submits an official request to repatriate, and the museum prepares an appropriate notice for publication in the Federal Register. In practice, however, some museums need additional time to prepare their collections for repatriation (often due to budgetary and staffing constraints), and they request that the tribe delay submission of an official claim to repatriate until

the museum is able to make ready the collection. In one case involving Jemez human remains, this delay lasted more than 6 years – enough time to raise suspicions on the tribal side that the museum was guilty of intentional foot-dragging. In the end, however, even that repatriation was successfully completed. Another issue that can cause delays at this stage is the past conservation practices used by the museum, as toxic chemicals such as arsenic, mercury, and pesticides were used to preserve organic artifacts in the past (Odegaard and Sadongei 2005). Prior to repatriation, objects must be tested for these contaminants, and if the tests are positive, a plan for appropriate disposition must be formulated.

Following submission of the tribe's official repatriation request, the museum publishes an appropriate notice in the Federal Register, after which the repatriation can officially take place (30 days after a Notice of Inventory completion for human remains and associated funerary objects is published; 90 days after publication of a Notice of Intent to Repatriate for sacred objects, unassociated funerary objects, or objects of cultural patrimony). While the museum is preparing the paperwork for publication, the tribal NAGPRA coordinator typically works on the logistics of the repatriation, including how the materials will be transported from the museum back to the reservation, where they will be stored (if necessary), and, in the case of human remains, where and when they will be reburied.

On the day of the return of the human remains and/or artifacts, a contingent from the tribe (often members of the CRAC and the Governor) visits the museum to officially take possession of the collections. This is often a somber occasion, with tribal members conducting the appropriate ceremonies prior to removal of the materials from the museum. The Governor then meets with museum staff members to sign the necessary legal paperwork, and the artifacts/human remains are loaded into a vehicle for transport. Depending on the size of the repatriation, this can either be a very short process involving a single car or a much more involved process involving multiple forms of ground and air transport. The 1999 repatriation of more than 2000 human remains from Pecos Pueblo held at Harvard's Peabody Museum of Archaeology and Ethnology required a tractor-trailer to transport the individuals more than 2,200 miles across the country.

At Jemez, once the objects or human remains return to the reservation, there is no single protocol that is followed. Some repatriated objects have been placed on display in the tribal museum (mainly ceramics). Others, particularly in the case of sacred objects and objects of cultural patrimony, are typically entrusted to traditional religious leaders for safekeeping and appropriate ceremonial use. The Jemez policy for human remains is always reburial. In theory the most desirable reburial location is the site from which the individuals were disinterred. However, because the excavations necessary for reburial could disturb additional graves if performed at the site itself, reburials often take place nearby but off-site. The locations chosen for these reburials are private, remote, and secret. A backhoe is employed to dig a deep pit in order to ensure that these individuals will not be disturbed again. Then tribal members, overseen by the *Fiscales* (appointed officials responsible for coordinating funerary activities), place the remains in the pit and perform a short ceremony. Finally the pit is refilled, and the reburial is complete. The ancestors have returned home.

Repatriation Acts: The Politics of Repatriation in North America

Joe Watkins
Archaeological and Cultural Education Consultants, Tucson, AZ, USA
Archaeological and Cultural Education Consultants, Takoma Park, MD, USA

Introduction

In North America, the National Museum of the American Indian Act and the Native American Graves Protection and Repatriation Act are the two laws that regulate the repatriation of materials to American Indian tribes. Since much has been written about these laws, Native American Graves Protection and Repatriation Act (see the entry on NAGPRA in this encyclopedia) will not be discussed in detail here; the reader is referred to numerous websites devoted to discussing these laws and their histories. Since the National Museum of the American Indian Act was the first of the repatriation acts, it will be discussed first, but since the Native American Graves Protection and Repatriation Act has had perhaps the most widespread impact on museums and anthropologists, it will be discussed in more detail.

Definition

Repatriation, in its very basic sense, is the process of returning something to its home country. More often than not, the items returned are soldiers or their remains following a war of some sort. However, in the sense of Indigenous populations, repatriation generally is used to refer to the return of particular classes of objects held within museum or government collections to the cultures from which they were acquired.

Historical Background

On November 19, 1620, Pilgrim explorers in search of the inhabitants of their new land happened across "a place like a grave." They dug into it and found "the bones and skull of a man [and] . . . the bones and head of a little child" along with cultural material placed with the bodies. Not content to leave the material alone, they ". . . brought sundry of the prettiest things away with us, and covered the corpse up again" (Heath 1963: 27–28). Only 8 days after the Pilgrims had anchored off Cape Cod, American Indian graves had already been plundered for their contents.

In the United States, American Indian concerns regarding materials in the collections of museums and government agencies reached a crescendo during the political unrest of the 1960s and 1970s when pan-Indian groups such as the American Indian Movement staged protests about the

storage and display of American Indian skeletal materials. American Indians distrusted archaeology and archaeologists; the American Indian Movement's disruption of excavations at Welch, Minnesota, in 1971 exemplifies the physical actions taken to confront the issue, as were organized protests aimed at getting American Indian human remains and sensitive material out of public displays such as the occupation of the Southwest Museum in Los Angeles in 1971. Additionally, tribal groups began addressing the desire for the repatriation of human remains and artifacts with the fight for the return of the Onondaga wampum belts from the State Museum of New York in 1969.

The National Museum of the American Indian Act (NMAIA) and Its Amendment

The passage of the National Museum of the American Indian Act (PL 101–185) in 1989 established the National Museum of the American Indian and also required the Smithsonian Institution to inventory, document, and, if requested, repatriate culturally affiliated human remains and funerary objects to federally recognized native groups. Congress amended the NMAI Act in 1996 to make it more closely conform to the language of the Native American Graves Protection and Repatriation Act (NAGPRA) passed by Congress in 1990.

The Native American Graves Protection and Repatriation Act (NAGPRA)

Public Law 101–601, the Native American Graves Protection and Repatriation Act (NAGPRA), affirms the rights of lineal descendants, Indian tribes, and Native Hawaiian organizations to custody of Native American human remains, funerary objects, sacred objects, and objects of cultural patrimony held in federal museums or agencies or in museums that receive federal funds.

Signed into law by President George Bush in November 1990, NAGPRA places the responsibility for compliance upon federal agencies and museums that receive federal funds. It required all federal departments, agencies, or instrumentalities of the United States (except for the Smithsonian Institution) to complete summaries and inventories of Native American materials in their control (including those held by nongovernmental repositories) and to ensure compliance regarding inadvertent discoveries and intentional excavations of human remains conducted as part of activities on federal or tribal lands.

The system outlined by these two statutes generally provides a framework for resolving issues surrounding the disposition of Native American human remains, funerary objects, sacred objects, and objects of cultural patrimony excavated or discovered on federal or tribal lands or held in federal or museum collections. Categories of materials that are eligible for return under the laws include (1) human remains of an individual whose identity is known, (2) culturally affiliated human remains, (3) associated and unassociated funerary objects, (4) sacred objects, and (5) objects of cultural patrimony. In addition, tribes may request the return of objects transferred to or acquired by museums and federal agencies illegally or under circumstances that render the museums' or federal agency's claim to them invalid.

Culturally affiliated human remains are defined in the legislation as human remains that share a relationship with a present-day Indian tribe that can be demonstrated based on a preponderance of available evidence. Associated and unassociated funerary objects are items that, as part of the death rites of a culture, are believed to have been intentionally placed with an individual of known affiliation at the time of death or later. The only distinction between whether a funerary object is considered unassociated or associated is whether or not the museum or federal agency has the human remains with which it was originally interred. Sacred objects are specific ceremonial objects that are needed by traditional Native American religious leaders in order to continue practicing their traditional Native American religions by present-day adherents. Objects of cultural patrimony are more difficult to define and vary among tribes. In general, they are cultural objects that were originally owned by the entire tribe rather than a single individual and which have an ongoing historical, traditional, or cultural

importance to the native group. Because the objects were tribally owned rather than individually owned, they cannot have been alienated, appropriated, or conveyed by any individual at the time they were acquired. An example of an item of cultural patrimony for American citizens would be the original signed copy of the Bill of Rights or the Liberty Bell.

Repatriation of Native American human remains and certain cultural objects may be made by lineal descendants of named individuals, federally recognized Native American tribes, federally recognized Native Alaskan villages, and Native Hawaiian organizations named in the Acts.

The Acts also required the establishment of special committees to monitor and review the process of inventory, identification, and repatriation covered by each specific law. The Review Committee established by each law reviews findings relating to the origin or the return of human remains and cultural objects. The committees also assist in resolving disputes between groups or between a group and the museum or agency regarding the disposition of collections.

Key Issues/Current Debates

Within repatriation, there are some issues that have arisen due to problems within NAGPRA, among them the failure of NAGPRA to prevent the perceived continuing desecration of American Indian human remains through further scientific study, the failure of NAGPRA to protect human remains on private land, the repatriation of materials from extremely ancient cultures, the ambiguous definition of "sacred objects" and "objects of cultural patrimony," the failure of NAGPRA to address the needs of nonfederally recognized tribes, and the disposition of "culturally unidentifiable human remains."

While NAGPRA itself does not allow scientific study as part of the repatriation process, it does allow study of the materials if necessary for the more correct disposition of the materials to an appropriate tribal claimant. Some tribes are opposed to many forms of scientific testing on human remains and see this as an unnecessary continuation of scientific information gathering at the expense of the tribes.

Many American Indian groups cannot understand why the graves protection portion of NAGPRA was not applied to all lands within the United States, rather than just to federal or tribal lands. Since the entire continent was at one time Indian land, tribes have a difficult time understanding why federal protection of graves should be extended only to federal or tribal lands. In a review of the legislative history of NAGPRA, Trope and Echo-Hawk note that many states have burials protection laws which provide guidelines to protect human graves (1992: 52). While human remains may be protected under various state laws, federal intervention on private land can sometimes been seen as a violation of the "takings clause" of the 5th Amendment to the Constitution if the land owner is somehow denied access to or free use of property without adequate compensation. Since the majority of land in the United States is held in private ownership, this limits the law's protection to the majority of situations where human remains and objects are encountered.

There are certain objects within museum collections that do not easily fall within the definition of "sacred" items or "objects of cultural patrimony." A Kiowa war chief named Satanta had a war shield that was given to him for his protection in battle, and it worked through his participation in more than a hundred battles. The shield hung in the Kiowa medicine lodge, and Satanta proudly displayed it after every battle for the Kiowa people to see. Even though the shield did not have a specific role in the practice of the Kiowa Sun Dance, the last Sun Dance of the Kiowa was delayed until the shield could be brought from its home to its place of honor. Before Satanta was taken to Texas for imprisonment, he gave the shield to his son, Gray Goose, who kept it until he died. Supposedly Gray Goose bequeathed the shield to the superintendent of the Anadarko Agency of the Bureau of Indian Affairs. Eventually the shield made its way to the Phoebe Hearst Museum in Berkeley, California. The museum

had a valid right to ownership, as indicated by the original accessions records. The shield is not sacred under the definition of the NAGPRA, since it never had a formal role within the tribe's traditional religion except within the practice of religion by an individual tribal member (Satanta). Neither is the shield an object of cultural patrimony under the definition of the NAGPRA, since it was an individually owned property that could be legally disposed of (sold or given away) by the owner. However, the shield is both sacred and an object of cultural patrimony to the Kiowa tribe and the family. It is believed to possess powers that were given it by its maker, and it was a part of the tribal cultural inventory relating to the Indian Wars of the 1860s and 1870s, as well as an important object related to one of the last war chiefs of the Kiowa. The descendants of Satanta did not want the shield to go to the Kiowa tribe for fear of its theft. Additionally, the family recognized that the museum had a legal claim to ownership of the shield based on the donation documents. Eventually, a compromise was worked out. The museum sent the shield on permanent loan to the Fort Sill Museum in Fort Sill, Oklahoma, where the family members can more easily visit it. The original museum still technically maintains ownership of the shield but the family does not have to fly to California to see it. It still plays an important role in the Kiowa family's history, even if it does not reside within their home.

There are multitudes of issues regarding the repatriation of objects from ancient cultures, depending on whether one is dealing with human remains or with cultural objects. In relation to human remains, the situation regarding Kennewick Man/the Ancient One is illuminating, while the situation regarding cultural property is well illuminated by the situation regarding the Spiro materials of eastern Oklahoma.

The situation regarding the human remains known alternately as "the Ancient One" or "Kennewick Man" is exemplary for the problems associated with extremely old human skeletal material. Kennewick Man (see Downey 2000; Thomas 2000) was the name given to a nearly complete set of human remains discovered in the Columbia River in 1996. Shortly before the remains were to be repatriated to the tribes in the area of the discovery, eight anthropologists filed suit in court to block the repatriation. The fact that the skeleton was not related to *any* recent human groups, especially any American Indian groups, made it more difficult to justify repatriating it to any particular Indian group and easier to justify continued study. The fact that the people who temporally follow show some resemblance to the Kennewick material hints that they *may* have derived some of their morphological characteristics from the population of which the Kennewick individual was a member. While there were certainly conflicts between the scientific possibilities raised by the discovery of a nearly complete skeleton such as "the Ancient One," the principle issue tested throughout the conflict has been the legal question of whether NAGPRA should apply to materials of such antiquity. Ultimately, the court held that the material known as the Ancient One did not meet the definition of "Native American" under NAGPRA and was therefore not subject to repatriation. In 2014, scientists were able to obtain aDNA material from the skeleton that indicated a genetic relationship with two Colville individuals who had provided DNA samples (Rasmussen et al. 2015). Ultimately, in 2016, Congress passed a law allowing transfer of the remains to the State of Washington, who then repatriated the material to the Tribes. Kennewick Man was reburied on February 18, 2017.

The disposition of objects from the Spiro Mounds of eastern Oklahoma (Watkins 2004) is a good example of the issues that arise when two groups with seemingly equal claims to materials (but divergent ideas about the disposition of those objects) interact with a willing museum. The University of Oklahoma controls artifacts that were collected from the Spiro Mounds, one of the best-known mound complexes in the southeastern United States with "...extraordinarily rich litter burials of the elite and the shameless looting of the burial mounds during the Depression" (Bense 1994: 223). While these artifacts are indeed special in their size and workmanship, they also meet the definition of "funerary objects" under

NAGPRA eligible for repatriation to culturally affiliated tribes. The tribes most likely to be culturally affiliated with the Spiro materials are the Wichita and Affiliated Tribes of Indians and the Caddo Tribe of Oklahoma. Each tribe has a "valid" claim to the artifacts based on the shared cultural component of the most likely recognizable Indian tribal group which created the artifacts, but each have an opposite idea of how the materials should be used. The museum continues to maintain control of the artifacts and displays some of them.

Additionally, the repatriation legislation only indirectly addresses materials associated with groups that are not currently "recognized" by the federal government to have the special relationship of an "Indian tribe" or Native American under the law through its "cultural unidentifiable" clause. Many tribes feel that nonfederally recognized American Indian tribes are no less Indian than their federally recognized counterparts, but others are afraid that to allow standing under NAGPRA would allow such groups to bypass the normally tedious process of federal recognition. While all tribes agree that human remains of unrecognized American Indian groups are have been and always will be American Indian, many are concerned about extending rights to groups under NAGPRA. In a statement prepared for the March 1997 Review Committee meeting in Oklahoma, NAGPRA representatives from seven tribes from southwestern Oklahoma – the Apache Tribe of Oklahoma, the Caddo Tribe, the Comanche Tribe, the Delaware Tribe of Western Oklahoma, the Fort Sill Apache, the Kiowa, and the Wichita and Affiliated Tribes – felt that repatriation should occur only to federally recognized groups. While they felt that human remains, regardless of affiliation, should not be left in museums, they expressed a concern that to repatriate human remains to nonfederally recognized tribes could potentially assign rights and authority to groups that have come into existence without a legitimate claim of continuity. The working group felt that the human remains associated with such groups should instead be repatriated to the federally recognized tribes on whose aboriginal lands the remains were found, with the Review Committee making decisions in cases of multiple tribes claiming the same ancestral lands.

The most current issue regarding NAGPRA is the disposition of "culturally unidentifiable human remains," defined under the law as human remains for which no lineal descendants or cultural affiliations have been determined. Under recent regulations, museums have been required to identify human remains which do not easily fall within other aspects of the repatriation regulations. These sets of human remains can fall into this category because they are of an age that prevents the adequate attribution to a specific culture (cultural affiliation) or tribal group and can belong to a known tribal group which is not currently a "federally recognized tribe," or the information regarding the location of the site where the human remains originated makes adequate determination of geographic information unreliable or unknowable. While each of these aspects which contribute to the adequate determination of which tribal groups should be able to request repatriation under the law, tribal groups believe that such materials should be returned to tribal groups rather than languish within museum collections until such time as the museum determines who should get them. In 2015, NAGPRA regulations concerning "unclaimed" materials (43 C.F.R. 10.7) were promulgated which allows a federal agency to transfer materials that have not been claimed by a tribal group to an Indian tribe or Native Hawaiian organization that is not a potential claimant. As a result, the Choctaw and the Chickasaw Nations of Oklahoma have worked together to initiate claims for ancestors in collections in their aboriginal homelands; the Michigan Anishinaabek Cultural Protection and Repatriation Alliance (MACPRA) Committee was formed to repatriate unclaimed materials known to have come from within the State of Michigan borders (http://www.macpra.org/mission/).

International Perspectives

Repatriation under the NMAIA and NAGPRA has been major influence on international perspectives regarding the repatriation and return of items

within museum and government agency collections which derive from Indigenous cultural groups. While there is nothing within these specific laws that require repatriation to non-American Indian, Alaska Native, or Native Hawaiian organizations, the laws serve as models for the continuing recognition of rights of Indigenous populations to their cultural heritage. In terms of International Repatriation, Article 12 of the UNESCO Declaration on the Rights of Indigenous People (United Nations 2006) is perhaps the more relevant document to be used in support of the rights of Indigenous peoples to the use and control of their ceremonial objects and the right to the repatriation of their human remains.

Future Directions

The repatriation of human remains and other items of importance to American Indian tribes will continue to occur so long as archaeologists continue to excavate archaeological sites. As new items are encountered in construction projects or within controlled excavation, human remains and their associated funerary objects will pass into and through federal agencies and museum collections. American Indian tribes will continue to work with federal agencies and museums to regain those items that have special meaning to their tribal cultures.

Internationally, more and more groups will probably continue to press for the return of human remains and special classes of objects from museums to be returned to the cultures of their origin. The utilization of international accords developed by organizations such as the United Nations and international archaeological organizations such as the Society for American Archaeology and the World Archaeological Congress will also contribute to the return of such objects to Indigenous groups and organizations.

Repatriation and Race in Indigenous Archaeology

Roger Echo-Hawk
Longmont, CO, USA

Introduction

The success of the racial Native American sovereignty movement during the second half of the twentieth century inspired a new narrative of hope among adherents to racial Indianhood (Wilkinson 2005). The passage of a law known as NAGPRA contributed greatly to this rekindling of optimism, helping to shore up the gradually sinking racial contract that had defined American identity since its founding as a nation.

After World War Two, the loosening of white privilege in American life and the challenges to racial whiteness as a socially acceptable form of bonding helped make possible civil rights initiatives for racial minorities. Moving slowly against white-pride racism, mainstream racial whites necessarily launched into an unacknowledged project to dismantle white identity systems. This meant that the currents of the American social project had begun to shift away from race as the central defining instrument of American identity.

Passed in 1990, the Native American Graves Protection and Repatriation Act (NAGPRA) served as a minor milestone in the historical evolution of racial practice in the United States. By that date, an emerging majority of Americans had become invested in a social narrative that rejected racial identity. These *faux whites* had little or no reason to engage in intraracial bonding – the true hallmark of racial identity. With no inducement to center their selfhood on race, these *white* people had become *faux white*. This process was invisible in an America that believed in race as a biological reality.

NAGPRA sought to strengthen the American racial contract. Swimming against the current of changing racial culture in American life, adherents to racial Indianhood relied on the structures of race in the American world as the basis for advocating passage of federal and state repatriation laws regulating the treatment of racially categorized *Native American* human remains and cemeteries. Race had come to America as a colonialist import, but now NAGPRA signified that racial Indianhood had become remythologized into an *indigenous* identity system.

As a matter of law, NAGPRA reflected an established American legal and political convention that subsumed diverse political entities under a race-based category termed *Indian tribes*. Rather than become integrated into the American union as states or continue as independent nations, *Indian tribes* joined the American political system as subaltern domestic dependencies with no formal constitutional role within either the federal system or state system. Laws, legislation, administrative directives, and court decisions pertaining to this group of racially defined quasi-sovereignties gradually fell under the racial rubric of *federal Indian law*. NAGPRA emerged from this colonialist legal tradition (Fig. 1).

Despite the fact that by 1990 anthropology held a shaky consensus that rejected race as a biological construction, NAGPRA helped to change the face of American anthropology, reshaping the academic relationship with racial Native America, particularly in archaeology (Killion 2007). Empowered by these developments and by the success of other pan-Indian initiatives, the intellectual and political leaders of Indian country entered the twenty-first century fully committed to the continued production of racial identity systems as an American cultural reality. Assisted by faux white supporters and encouraged by an academic preference to confine challenges to race to technical gray literature, racial Indians had no reason to question race. This ensured that racial Indians would deliberately link their social fortunes to the fate of race in America.

NAGPRA authorized racial Indian sovereign governments and Native Hawaiian organizations to claim culturally affiliated human remains,

Repatriation and Race in Indigenous Archaeology, Fig. 1 Billboard for a tourist attraction near Salina, Kansas. The State of Kansas and a coalition of tribes led by the Pawnee Nation closed this private business in 1990. (Photograph by Linda Echo-Hawk, March 1988)

funerary objects, sacred objects, and objects of cultural patrimony from US federal agencies and from museums receiving federal funding. It also covered new discoveries on US federal lands and within racially designated Native American sovereign homelands.

Federal funding became available in 1994 to help carry out NAGPRA, and in 1995 federal regulations implementing the law were issued by the National Park Service (NPS). Between 1994 and 2010, a total of 660 grants were awarded to racial Indian sovereignties (*Indian tribes*), Native Hawaiian organizations, and museums (National NAGPRA n.d.). These grants funded a variety of NAGPRA implementation projects, which typically involved hiring staff and consultants, purchasing equipment, and paying travel expenses.

Tribal delegations became a common sight at museums across the United States, and some major museums made NAGPRA implementation a part of the museum's public mission. At the Denver Art Museum, for example, the Native Arts Department hosted its 100th post-NAGPRA racial Indian delegation in June 2002 – a daylong NAGPRA training workshop with the Nooksack tribe. Almost half of those visits were funded by National Park Service NAGPRA grants to the Denver Art Museum, and most of the other tribal delegations were funded by NPS grants to racially classified sovereigns. These NPS-funded projects focused on assessing the applicability of the law to collections of human remains and several categories of cultural items.

Key Issues and Current Debates

Sparked primarily by moral concerns over museum collections of racially identified Native American human remains, NAGPRA took shape during the late 1980s as a response by the United States to a national social justice movement among adherents to racial Indianhood (Preucel 2011). During the 1970s and early 1980s, social momentum on this issue steadily grew. But racial Indian attitudes about human remains in museum collections received little systematic acknowledgement from either racial sovereign governments or from anthropologists. The 1980s saw a swift expansion of public discourse on the issue among racial Indians and in anthropological literature (Green and Mitchell 1990).

By the time NAGPRA became law in 1990, growing outrage regarding museum collections of racially identified Native American human remains had generated a powerful sense of unity among many self-identified Indians. As racial sovereignties began reburying human remains and repatriating cultural items from museum collections, NAGPRA-related storytelling entered

the central bonding narratives of racial Indianhood. *Repatriation* among Indians signified the successful assertion of race-based social power; NAGPRA affirmed that racial Indianhood could produce empowering results for racial Indians in America.

Anthropologists were less unified in their response to passage of NAGPRA. It is arguable that a majority of anthropologists – especially cultural anthropologists – quickly adjusted to the new authority of racial Indian sovereignties under NAGPRA, seeing themselves primarily as students of racial Indian cultures rather than as imperialistic white-pride oppressors. But through the decade that followed passage of the law, significant groups of anthropologists and Indians worked to concurrently craft a national narrative of science-versus-religion polarization.

Prominent segments of the anthropological community fretted about the potential negative consequences of the law for academic scholarship, worrying particularly about the potential impact on archaeological inquiry, museum collections, and biological science. They feared that antiscience Indian sovereigns would ally with sympathetic US federal bureaucrats to invasively cripple useful research.

When Indians worried about the law, they suspected that entrenched white racism would thwart an important Indian quest for social justice. Encountering opposition from anthropologists and sensing resentment from academia, racial Indians suspected that white racism would limit repatriation and undermine tribal authority.

Simmering resentments between these elements of the anthropological community and Indian country flared in the wake of the 1996 discovery of ancient human remains in the waters of the Columbia River in Washington. A group of anthropologists successfully sued to prevent *Kennewick Man* from being turned over to a coalition of local racial Indian sovereignties. Reporting on this case, the American media commodified NAGPRA as an exciting culture war battleground, ignoring the fact that a vast collaborative interfacing between racial Indians and archaeologists was well underway across America (Dongoske et al. 2000).

The Kennewick Man situation thrust a facade of extremist voices to the forefront of this cultural interface. Among Indians who distrusted academic anthropology, the Kennewick Man fiasco enflamed suspicions that the academic world was bent on crafting surreptitious plots to undermine an empowered Native America. Among NAGPRAphobic anthropologists, the Kennewick Man fiasco enflamed suspicions that Indian country was bent on replacing science with religion.

In *Skull Wars* (2000), archaeologist David Hurst Thomas sought to reframe the Kennewick Man battleground into a new anthropological cultural consensus. Pondering the history of relations between anthropologists and Indians, this influential book explained the anthropological rejection of race, yet it also adopted a deferential tone to the American racial status quo. In this narrative of Indians versus whites, Vine Deloria Jr. was poised as the leading spokesperson for Indians, while Thomas set up himself as the introspective voice of anthropology. *Skull Wars* argued that anthropologists should develop partnerships with Indians. It also suggested that academic scholars should retain professional analytical skepticism toward racial Indian ambitions related to implementation of NAGPRA.

In *Indigenous Archaeology* (2000), Joe Watkins framed the archaeological component of the NAGPRA culture war as a clear divide separating the practices of white archaeologists from the values of racial Indians. Acknowledging that the master narrative of racial Indianhood included many suspicions about archaeology, Watkins suggested that the future growth of a more fully empowered *indigenous archaeology* would be dependent upon the willingness of racial whites to cede meaningful control of archaeology to racial Indians.

Watkins (2000: 105–15) presented a case study of the Pawnee Nation's efforts to repatriate human remains, contrasting the cooperative tone that unfolded in Kansas with an acrimonious dispute that took place in Nebraska. Launched by the Native American Rights Fund in Colorado, the Pawnee repatriation project ultimately helped give rise to NAGPRA. Carefully orchestrating legislative initiatives, negotiations, and historical

research, the Pawnee project showed that the American public supported racial Indian repatriation.

Prior to the 1990s, little dialogue occurred between archaeologists and Pawnees despite the extensive investigations of Pawnee sites that began during the 1920s. As an outcome of the Pawnee repatriation program, new relationships developed that included Pawnees participating in archaeology and conducting research projects in partnership with archaeologists – the first visit by archaeologists with the leadership of the Pawnee Nation occurred in the post-NAGPRA era. Despite this more positive atmosphere, cooperative projects remained sporadic. Indeed, one Pawnee repatriation activist articulated the dominant Pawnee attitude toward archaeology at the end of the 1990s, characterizing the entire discipline as *oppressive and sacrilegious* (Riding In 2000: 106).

Seeking to promote a more collaborative interfacing of the interests of academic archaeology and racial Indians, Joe Watkins and his colleagues in 2001 founded the Closet Chickens. This group took shape as an informal association of self-identified Indian archaeologists and carefully vetted nonracial faux white supporters. Standing up for implementation of NAGPRA by racial Indian sovereignties, the social idealism of the Closet Chickens attached positive meanings to the empowerment of racial Indianhood, but this idealism also promoted racialism in an academy that was slowly abandoning the prerogatives of white racial identity.

The Kennewick Man case was decided in 2002 and upheld in 2004 by the 9th Circuit Court of Appeals. These court decisions gutted the consultation provisions of NAGPRA, dismissed oral traditions, undermined joint claims by multiple claimants, and denied the racial assignment under NAGPRA of Kennewick Man as *Native American*. Efforts soon followed to maneuver around the Kennewick Man court rulings on the racial definition of *Native American* by amending NAGPRA. These efforts failed. But an expansive mechanism for dealing with the NAGPRA class of *culturally unidentifiable* racially identified Native American human remains became finalized in the US federal regulations in 2010. This promoted the repatriation of unaffiliated racially designated Native American human remains to racial Indian tribal claimants and Native Hawaiian organizations.

Despite the confrontational tone set by the Kennewick Man case, NAGPRA eventually helped to establish a new consensus throughout the discipline of American archaeology. Archaeologists increasingly understood and accepted that the accommodation of racial sovereignties would make the profession more inclusive of racial Indian viewpoints. The term *multivocal archaeology* became adapted to characterize this new inclusiveness. But the emergence of multivocal archaeology did not necessarily mean that Indian views on oral literature would gain easy admittance to academic constructions of history.

The NAGPRA cultural affiliation standard encouraged the use of oral traditions, heartening racial Indians who often bonded through complaints that archaeology disrespected oral traditions. Few scholars chose to take up this challenge, however, and post-NAGPRA literature saw only a handful of peer-reviewed publications that integrated the study of oral traditions and the archaeological record (Echo-Hawk 2000; Whiteley 2002). Though such research would seem likely to appear in time, talk of a *separate but equal* paradigm also took shape. The culturally respectful pedagogy of multivocalism opened the door for the comparison of archaeological models of prehistory and Indian traditions about ancient history, but mainstream archaeology seemed content to treat these as separate racially segregated *ways of knowing*.

During the late twentieth century, Indian activists who sought to advance the Indian sovereignty movement by villainizing archaeology often felt suspicious of Indians who took up anthropology. These Indian activists found it easy to ignore the vast changes that reshaped the profession in the decades after passage of NAGPRA (Riding In 2000; Echo-Hawk 2010: 255–71). Racial Indians entering the discipline of archaeology understood that their social position could sometimes be precarious. Many found a sense of balance by policing archaeology via ethical precepts influenced by

NAGPRA. Some helped their communities develop new ways of addressing archaeological inquiry by implementing tribal historic preservation programs. Drawing on the new expertise of these racial Indian archaeologists, racial Indian sovereignties like the Navajo Nation began building their own archaeology programs.

Indian archaeologists embraced the pan-Indian narrative on NAGPRA as a law pertaining to race-based social justice. This meant they also had to preferentially bond through the doctrines of racial Indianhood. Rather than help Indian people wrestle with the anthropological consensus rejecting race, Indian anthropologists chose to maintain a code of professional silence about the nature of American racialism. This communal vow of silence became a new tenet of racial Indianhood. Indian intellectuals conjointly handed down to their heirs an unwavering commitment to race, unaffected by the changing definitions of race in the American world beyond Indian country.

Faux white supporters of social justice for racial Indians were less unified in maintaining silence about the true nature of race (see Thomas 2000; Echo-Hawk and Zimmerman 2006; Colwell-Chanthaphonh 2009; Preucel and Mrozowski 2010: 286–7). The faux white supporters of Indians did not practice race themselves. They did not engage in racial bonding with other members of their own assigned racial group. In fact, they had a professional suspicion of race as a discredited theory of human biological diversity. Unlike colleagues who acted purely as cheerleaders for Indian racialism, urging Indians to stay faithful to race while they themselves abandoned it, these authors seemed willing to experiment with a more nuanced semi-postracial position. They didn't believe in race and they said so, but they still had a heartfelt commitment to NAGPRA and the production of race-based social justice.

Repatriation empowered racial Indianhood, and race helped Indian tribes assert control over human remains and repatriate long-lost cultural items, so the doing of race could not be cleanly separated from the making of social justice. The two were intertwined. For this reason, faux whites could not support one and reject the other. But a vast weakening of white racial bonding and an undermining of white privilege had been unfolding slowly for decades, pushed along by the American civil rights movement. The white abandonment of race declared that the American racial contract was somewhere in the process of getting swept to the edges of American life. In a slowly dawning postracial America, would Indians always hold fast to the promises of racial identity?

As an articulation of over two centuries of entrenched American racialism, the passage of NAGPRA added considerable momentum to the racial Indian sovereignty movement. Renewing a sense of enthusiasm for American racialism among Indian practitioners of race, the NAGPRA narrative of success inspired Indians to work to buttress the wavering American racial consensus. Guided by an energetic investment in the tenets of race, Indians failed to understand the detachment from racial bonding that had emerged among racial whites.

The legal philosophers of racial Indianhood understood that the social project that led to NAGPRA had to do with exploiting race. The power of racial bonding had been applied to uphold the status of Indian tribes in the American political system as racially defined domestic dependent nations. Indian lawyers also believed that the strengthening of this status would lay the foundation for the production of a viable political independence movement. In fact, the repatriation of cultural items and human remains under NAGPRA did encourage many racial Indian sovereignties to recalibrate their social agendas and reinvigorate their cultural heritages.

The successes of NAGPRA meant much for many racial Indian sovereignties. But these successes did not rewrite the truths that really shaped the status of Indians in the American political system. In affirming the empowerment of race through NAGPRA and in attempting to keep faux white Americans bound to their abandoned racial compact, Indians necessarily reaffirmed the status of *Indian nations* in the United States as racially defined quasi-sovereignties. Indian lawyers had built an active sovereignty movement by

looking to the US constitution to protect Indian rights, but this same constitution mentioned racial Indians twice and racial whites not at all. By law, Indians would never have the freedom enjoyed by whites, who could freely abandon race, and were doing so in large numbers by the end of the twentieth century.

Rejecting the nonracial social option embraced among faux whites, Indians rejected freedom from the tyranny of race. Attaching their racial Indian governments to the colossal sinking façade of race through NAGPRA and other pan-Indian initiatives, Indian leaders opted for continued dependence on the US federal trust relationship. There would be no confrontation of a fundamentally unfair system in which all Americans could abandon race except racial Indians. There would be no challenge to an undemocratic system of sovereigns in which racially identified Indian sovereigns lacked official political representation and therefore had no formal voice in their own fate.

Holding fast to the fading fortunes of American racialism, Indians left untapped a huge aquifer of moral authority that could be potentially accessed by strategically confronting the imposition of racial Indianhood under the racialist traditions of US federal Indian law. The Indian sovereignty movement would remain a project devoted to race. Indians would accept dependence within the American racial system over the more uncertain quest for full sovereign independence. Continuing the project of cultivating race as a convenient source of social power, Indian leaders began to repackage racial Indianhood into a more international form of racial indigenism – even aspiring to harvest ideological assistance from the United Nations (Echo-Hawk 2010: 426–60).

Embracing race through repatriation and NAGPRA, adherents to racial Indianhood entered the twenty-first century as optimistic stewards of a race-based sovereignty movement. They won many victories by investing in the social authority of the American racial narrative. Even as this metanarrative steadily evaporated from the hearts of other Americans, Indians persevered, clasping vanishing dreams of sovereignty as they trekked onward to the unknown destinations of race.

Repatriation and Restitution of Cultural Property: Relevant Rules of International Law

Tullio Scovazzi
International Law Department of Law, University of Milano-Bicocca, Milan, Italy

Introduction

The logical and legal link between appropriation and restitution of cultural properties is self-evident. If appropriation of the properties is illegal, there is an obligation to return them. Any State which is responsible of an internationally wrongful act is bound, first of all, to reestablish the situation that would have existed if the act had not occurred.

The question of restitution of cultural properties (A distinction is sometimes made today between "return," used in a general sense, and "restitution," used for stolen or illegally exported properties. The term "repatriation" is also used. But such questions of terminology do not seem important.) is the subject matter of a number of international treaties which have a world scope of application. Their main provisions can today be considered as belonging also to customary international law. The trend toward the restitution is growing, as the result of the application of principles having also a moral and cultural character.

Key Issues

Restitution After War

The experience of the pillages occurred during the Second World War influenced treaty provisions

relating to the protection of cultural heritage in time of war. Article 33 of the Convention on the Protection of Civilian Persons in Time of War (Geneva, 1949) prohibits in general pillage and reprisals against the property of protected persons. Article 4, para. 3, of the Convention for the Protection of Cultural Property in the Event of Armed Conflict (The Hague, 1954) (131 States are parties to it.) concluded within the framework of the United Nations Educational, Scientific and Cultural Organization (UNESCO), prohibits "any form of theft, pillage or misappropriation of, and any acts of vandalism directed against, cultural property," as well as the requisition of movable cultural property situated in the territory of another party. Article I of the First Protocol (The Hague, 1954) (109 States are parties to it.) to the Convention binds a State Party "to prevent the exportation, from a territory occupied by it during an armed conflict, of cultural property" (Art. I, para. 1) and "to return, at the close of hostilities, to the competent authorities of the territory previously occupied, cultural property which is in its territory, if such property has been exported in contravention of the principle laid down in the first paragraph." The provision adds that "such property shall never be retained as war reparations" (Art. I, para. 3). Under Art. 9, para. 1, of the Second Protocol (The Hague, 1999) (76 States are parties to it.) to the Convention, "(. . .) a Party in occupation of the whole or part of the territory of another Party shall prohibit and prevent in relation to the occupied territory: *a*. any illicit export, other removal or transfer of ownership of cultural property; *b*. any archaeological excavation, save where this is strictly required to safeguard, record or preserve cultural property; c. any alteration to, or change of use of, cultural property which is intended to conceal or destroy cultural, historical or scientific evidence."

Irrespective of the application of any treaty, the obligation to return cultural properties removed in time of war or during military occupation is confirmed by United Nations Security Council Resolution 1483 of 22 May 2003, dealing, inter alia, with measures to facilitate the return of cultural properties illegally removed from Iraq after 6 August 1990 (in fact, after the said date, Iraq underwent periods of war, periods of peace, and periods of military occupation). According to the resolution, "(. . .) all Member States shall take appropriate steps to facilitate the safe return to Iraqi institutions of Iraqi cultural property and other items of archaeological, historical, cultural, rare scientific, and religious importance illegally removed from the Iraq National Museum, the National Library, and other locations in Iraq since the adoption of resolution 661 (1990) of 6 August 1990, including by establishing a prohibition on trade in or transfer of such items and items with respect to which reasonable suspicion exists that they have been illegally removed, and calls upon the United Nations Educational, Scientific, and Cultural Organization, Interpol, and other international organizations, as appropriate, to assist in the implementation of this paragraph" (para. 7).

Such an obligation was restated by Security Council Resolution 2199 of 12 February 2015, which also applies to cultural properties removed from Syria since 15 March 2011. Here the Security Council also noted with concern "that ISIL [= Islamic State in Iraq and the Levant], ANF [= Al-Nusrah Front] and other individuals, groups, undertakings and entities associated with Al-Qaida, are generating income from engaging directly or indirectly in the looting and smuggling of cultural heritage items from archaeological sites, museums, libraries, archives, and other sites in Iraq and Syria, which is being used to support their recruitment efforts and strengthen their operational capability to organize and carry out terrorist attacks" (para. 16).

Recently, under Resolution 2347 (2017) of 24 March 2017, the Security Council stressed the existence of a vicious circle, explicitly stating that the destruction and looting of cultural properties, besides being a likely consequence of war, can also be in itself a cause of war, insofar as it "can fuel and exacerbate conflict and hamper post-conflict national reconciliation, thereby undermining the security, stability, governance, social, economic and cultural development of affected States" (preamble).

Restitution in Time of Peace

The issue of restitution of cultural properties is today also related to the problem of illegal trafficking in time of peace. In this regard, the first matter to be addressed is the apparently simple question of determining in what cases "illegal trafficking" really is "illegal." While such a qualification depends on a given national legislation, in cases of transboundary movements of cultural properties, at least two different domestic legal systems are involved, namely, that of the State of origin and that of the State of destination, to which may sometimes be added that of the State of transit. The relevant regimes may be different, depending on the legislation of the States involved.

Under a universally recognized principle of law, the theft, that is, the appropriation of properties without the consent of the owner, is a crime subject to criminal sanction and cannot create a valid title for the thief over the stolen objects. However, even in the case of theft, the domestic legislation of different countries may vary as to whether the rights of a third good faith purchaser should be protected and as to whether the statute of limitation (called also acquisitive prescription) could apply in favor of the possessor after the passing of a certain number of years from the crime. Here two maxims taken from Roman law – *beati possidentes* (possessors have priority) and *nemo plus iuris transferre potest quam ipse habet* (nobody can transfer more rights than those that he has) – play one against the other.

In the case of cultural objects fortuitously found and subsequently removed, national legislation may vary also as to who is their owner, either the private owner of the land or the finder or the State as the trustee of a public interest. Similar differences may exist in the case of objects found in excavations. If the objects are found on the seabed, the alternative as to the holder of title is between the finder and the State.

In the case of illegal movements, the picture becomes more complex because they may be the result not only of thefts but also of the violation of domestic legislation which prohibits or limits the export of cultural properties from the national territory. National legislation for this purpose has been adopted by a number of States, especially those that are rich in cultural heritage (One of the first instances in this regard is a decision taken in 1602 by the grand duke of Tuscany, subjecting to a license the export of "good paintings" and prohibiting altogether the export of the works of 19 selected masters, namely, "Michelangelo Buonarroti, Raffaello Sanzio, Andrea del Sarto, Mecherino, Rosso Fiorentino, Leonardo da Vinci, Franciabigio, Perino del Vaga, Jacopo da Pontormo, Tiziano, Francesco Salviati, Bronzino, Daniele da Volterra, Fra Bartolomeo, Sebastiano del Piombo, Filippino Lippi, Correggio, Parmigianino, Perugino."). Rules which prohibit or restrict or submit to an authorization the export of cultural properties can be violated irrespective of a theft and even by the owner himself (for instance, if he delivers the object to a buyer abroad or takes the object with him when transferring his residence abroad). However, the legislation of the State of destination may consider as legal the import of such properties, as if they were any other commercial good, and may refuse to apply a foreign legislation that prohibits or limits their export. Moreover, the definition of cultural property and the kinds of objects belonging to this category may vary depending on the national legislation involved.

It is evident that only a generally accepted regime adopted at the international level could overcome the problems posed by the differences in domestic legislation as regards international movements of cultural properties. To achieve this objective, two treaties of a universal scope of application have been concluded and are today in force, namely, the Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Properties (Paris, 1970) (136 States are parties to it.), concluded within the framework of UNESCO, and the UNIDROIT (International Institute for the Unification of Private Law) Convention on Stolen or Illegally Exported Cultural Objects (Rome, 1995) (42 States are parties to it.).

Taking into account the importance of cultural properties, the 1970 Convention sets forth the

duty of every State to respect both its own cultural heritage and that of other countries:

> Considering that cultural property constitutes one of the basic elements of civilization and national culture, and that its true value can be appreciated only in relation to the fullest possible information regarding its origin, history and traditional setting,
>
> Considering that it is incumbent upon every State to protect the cultural heritage existing within its territory against the dangers of theft, clandestine excavation, and illicit export,
>
> Considering that, to avert these dangers, it is essential for every State to become increasingly alive to the moral obligations to respect its own cultural heritage and that of all nations (...). (preamble)

The basic assumption of the 1970 Convention is that illegal trafficking must be condemned and fought because it impoverishes the cultural heritage of the States of origin of the objects:

> The States Parties to this Convention recognize that the illicit import, export and transfer of ownership of cultural heritage is one of the main causes of the impoverishment of the cultural heritage of the countries of origin of such property and that international co-operation constitutes one of the most efficient means of protecting each country's cultural property against all the dangers resulting there from. (Art. 2, para. 1)

The properties to which the 1970 Convention applies are those that belong to the categories listed in detail in Art. 1 and that have a specific link with a certain State, as specified in Art. 4 ("The States Parties to this Convention recognize that for the purpose of the Convention property which belongs to the following categories forms part of the cultural heritage of each State: (a) cultural property created by the individual or collective genius of nationals of the State concerned, and cultural property of importance to the State concerned created within the territory of that State by foreign nationals or stateless persons resident within such territory; (b) cultural property found within the national territory; (c) cultural property acquired by archaeological, ethnological or natural science missions, with the consent of the competent authorities of the country of origin of such property; (d) cultural property which has been the subject of a freely agreed exchange; (e) cultural property received as a gift or purchased legally with the consent of the competent authorities of the country of origin of such property."). The parties recognize the "indefeasible right" of each of them "to classify and declare certain cultural property as inalienable which should therefore *ipso facto* not be exported" (Art. 13, *d*). They are bound to introduce a specific certificate in which the exporting State specifies that the export of the cultural property in question is authorized and to prohibit the export of such property unless accompanied by it. They undertake to prevent museums and similar institutions within their territories from acquiring cultural property originating in another State Party which has been illegally exported (Art. 7, *a*). They also undertake to prohibit the import of cultural property stolen from a museum or a religious or secular public monument or similar institution in another State Party (Art. 7, *b*, i) as well as, at the request of the State Party of origin, to recover and return any such cultural property, provided that the requesting State pays just compensation to an innocent purchaser or to a person who has valid title to such property (Art. 7, *b*, ii).

Although very important for fostering international cooperation in the fight against illicit trafficking, the 1970 Convention has some limits. It does not have a retroactive character, applying to properties involved in illicit movements after the entry into force of the Convention for both the State parties concerned. It covers only certain kinds of illicit movements. For instance, the interdiction to acquire cultural properties illicitly imported is limited to museums, and the obligation to return is limited to cultural properties stolen from museums or similar institutions, without extending to cases where private individuals have been the victims or where the objects have been illegally excavated.

While the 1970 Convention envisages diplomatic action at the interstate level to achieve the return of cultural properties, the UNIDROIT Convention aims at providing individual victims with the right to bring proceedings before domestic courts for the return of stolen or illegally exported cultural objects. Under the UNIDROIT Convention, the illicit trade in cultural objects causes an irreparable damage which

also affects the heritage of all peoples. It follows that the return of such objects to the States of origin serves the interest of all. In fact, the States parties declare themselves

> deeply concerned by the illicit trade in cultural objects and the irreparable damage frequently caused by it, both to these objects themselves and to the cultural heritage of national, tribal, indigenous or other communities, and also to the heritage of all peoples, and in particular by the pillage of archaeological sites and the resulting loss of irreplaceable archaeological, historical and scientific information,
>
> Determined to contribute effectively to the fight against illicit trade in cultural objects by taking the important step of establishing common, minimal legal rules for the restitution and return of cultural objects between Contracting States, with the objective of improving the preservation and protection of the cultural heritage in the interest of all. (preamble)

The UNIDROIT Convention clearly provides that "the possessor of a cultural object which has been stolen shall return it" (Art. 3, para. 1) and that a State Party may request the court or another competent authority of another State Party "to order the return of a cultural object illegally exported from the territory of the requesting State" (Art. 5, para. 1). Specific provisions, which are subject to certain exceptions, apply as regards the time limitation of claims for restitution or return. Another provision specifies the cases where the return of illegally exported objects must be ordered:

> The court or other competent authority of the State addressed shall order the return of an illegally exported cultural object if the requesting State establishes that the removal of the object from its territory significantly impairs one or more of the following interests:
>
> (a) the physical preservation of the object or of its context;
>
> (b) the integrity of a complex object;
>
> (c) the preservation of information of, for example, a scientific or historical character;
>
> (d) the traditional or ritual use of the object by a tribal or indigenous community,
>
> or establishes that the object is of significant cultural importance for the requesting State. (Art. 5, para. 3)

Under certain conditions, the good faith possessor of a stolen cultural object or of an illegally exported object is entitled to a fair and reasonable compensation (Art. 4, para. 1, and Art. 6, para. 1). Also the UNIDROIT Convention has no retroactive application.

In all cases where the 1970 Convention or the UNIDROIT Convention are not applicable, for *ratione materiae*, *ratione personae*, or *ratione temporis* reasons, use can be made of the consultative services of the Intergovernmental Committee for Promoting the Return of Cultural Property to Its Countries of Origin or Its Restitution in Case of Illicit Appropriation (ICPRCP), provided that the property has "a fundamental significance from the point of view of the spiritual values and cultural heritage of the people of a Member State or Associate Member of UNESCO" and "has been lost as a result of colonial or foreign occupation or as a result of illicit appropriation" (Art. 3, para. 2, of the Statutes of the Committee). As set forth in Art. 4, paras. 1 and 2, of its Statutes, the ICPRCP is entrusted with the responsibility for "seeking ways and means of facilitating bilateral negotiations for the restitution or return of cultural property to its countries of origin" and "promoting multilateral and bilateral co-operation with a view to the restitution and return of cultural property to its countries of origin." By Recommendation No. 4 of 23 September 2010, the ICPRCP adopted a procedure for mediation and conciliation within its framework.

Future Directions

An Evolutionary Trend

In the last years, an evolutionary trend has developed toward the restitution of removed cultural heritage to countries of origin (for some relevant instances, which cannot be recalled hereunder because of space constraints, see Sandholtz 2007; Nafziger and Scovazzi 2008; Nafziger and Nicgorski 2009; Scovazzi 2011: 341). The trend applies in time of both war and peace.

The evolutionary trend is based on a number of principles that are located in the space between morality and law and that can be instrumental in addressing the shortcomings of multilateral treaties in force regarding the restitution of cultural properties, in particular their non-retroactive character and the fact that they can create rights and obligations only for the State parties.

The principles in question include the principle of non-exploitation of the weakness of another subject for cultural gain, which applies to situations of persecution, war, colonial domination, and foreign occupation or to situations involving indigenous peoples. This principle has also inspired the legislation enacted by certain countries on property looted to victims of the Holocaust (e.g., the *Holocaust (Return of Cultural Objects) Act 2009* of the United Kingdom), on the basis of the 2000 Vilnius Declaration on Holocaust Era Looted Cultural Assets.

Also relevant is the principle of preservation of the integrity of cultural contexts, which is deeply rooted in the nature of cultural heritage, especially as regards properties having an emblematic character for the country of origin. To divide is to destroy (*diviser c'est détruire*), as the French scholar Antoine-Chrysostome Quatremère de Quincy wrote already in 1796 in his book (*Lettres sur le préjudice qu'occasionneroient aux Arts et à la Science, le déplacement des monumens de l'art de l'Italie, le démembrement de ses Ecoles, et la spoliation de ses Collections, Galeries, Musées,* etc.), against the looting by France of paintings, statues, and manuscripts found in the occupied Italian States. Cultural properties have a special status and cannot be treated as any other commercial good. There is very little merit in the attitude of those who, in the name of an alleged principle of "cultural internationalism," plead for an almost uncontrolled movement of cultural properties (see Merryman 1986: 847). It is not by chance that such movement goes always in the same direction, following the rules of the market, to the benefit of those who can invest huge amounts of money in purchasing foreign cultural properties and to the detriment of the cultural identity of the countries of origin.

These principles, which play in favor of the State of origin of cultural properties, could be balanced against other considerations, which may play in favor of the State of destination, such as the contribution given by the latter for the preservation of the properties in question and the time elapsed since the removal. The objective is to reach an equitable solution for each particular case in the light of all the relevant circumstances.

Settlements negotiated by the parties concerned can only strengthen the efforts to achieve equitable solutions. Interesting in this regard are the agreements on the return of cultural properties concluded in the last years by the Italian Ministry of Cultural Properties and Activities with a number of cultural institutions located in the United States, such as the Metropolitan Museum of Art of New York, the Princeton University Art Museum, the Paul Getty Museum of Los Angeles, and the Museum of Fine Arts of Boston. The agreements provide for the return of cultural properties that Italy claims were illegally excavated in the national territory and sold clandestinely outside the country. The museums accept to transfer to Italy the requested items while rejecting any accusation that they had knowledge of their alleged illegal provenance. The second, but not secondary, objective of the agreements is to promote cooperation between the parties by temporary loans to the museums of objects of equivalent value, joint activities of excavations, and exchange of information about restorations.

The present trend goes mainly in the direction of the restitution of cultural properties to the countries of origin. Moral and cultural principles that dictate the restitution are being progressively transformed into legal rules. The trend has probably not yet reached the final stage when a body of new customary rules on restitution of cultural properties is definitely created. But it can be considered as already being within the dynamics of the evolution of international law (see Borelli and Lenzerini 2012; Francioni and Gordely 2013).

Repatriation of Cultural Property in the United States: A Case Study in NAGPRA (USA)

Joe Watkins
Archaeological and Cultural Education Consultants, Tucson, AZ, USA
Archaeological and Cultural Education Consultants, Takoma Park, MD, USA

Introduction

In the United States, the Native American Graves Protection and Repatriation Act of 1990 ("NAGPRA" hereafter) created mechanisms whereby individuals and federally recognized tribes could request the return of human remains, funerary objects, sacred objects, and items of cultural patrimony from museums and federal agencies. These processes have allowed tribal groups to obtain various classes of human remains and material artifacts from federal museums and federal agencies, as well as those institutions which receive federal funding.

Definition

The following definitions are found on the National NAGPRA Glossary (n.d.) at http://www.nps.gov/nagpra/TRAINING/GLOSSARY.HTM. "Human remains" are generally considered to be "(t)he physical remains of the body of a person of Native American ancestry. The term does not include remains or portions of remains that may reasonably be determined to have been freely given or naturally shed by the individual from whose body they were obtained, such as hair made into ropes or nets." "Funerary objects" are defined as "(o)bjects that, as a part of the death rite or ceremony of a culture, are reasonably believed to have been placed with individual human remains either at the time of death or later." If "both the human remains and associated funerary objects are presently in the possession or control of a Federal agency or museum," the funerary objects are considered to be "associated funerary objects." Those funerary objects "for which the human remains with which they were placed intentionally are not in the possession or control of a museum or Federal agency" are considered to be "unassociated funerary objects."

In NAGPRA, "sacred objects" are defined as "(s)pecific ceremonial objects which are needed by traditional Native American religious leaders for the practice of traditional Native American religions by their present day adherents." Additionally, an "object of cultural patrimony" is defined as "(a)n object having ongoing historical, traditional, or cultural importance central to the Native American group or culture itself, rather than property owned by an individual Native American, and which, therefore, cannot be alienated, appropriated, or conveyed by any individual regardless of whether or not the individual is a member of the Indian tribe or Native Hawaiian organization and such object shall have been considered inalienable by such Native American group at the time the object was separated from such group."

Historical Background

In the United States, the passage of Public Law 101-601, the Native American Graves Protection and Repatriation Act (hereafter NAGPRA), in 1990 signaled a change in the level of interaction between archaeologists, biological anthropologists, museums and federal agencies, and American Indian tribal groups not seen previously. Prior to the law's passage, American Indian groups lobbied to regain materials that had been taken, collected, or placed into museums of federal agency control. Often such materials were collected by researchers or explorers into relatively unknown regions; other times, materials were obtained under questionable practices by explorers, researchers, or even military personnel.

The passage of NAGPRA was not without controversy, as particular archaeologists lamented about the destruction of archaeology as a possible outcome of the legislation. Clement Meighan was quoted as saying that repatriation agreements "... assume all Indian remains of whatever age are the property of contemporary claimants and that it doesn't matter how old things are" (1992: 39). Others, including the museum profession, feared that the passage of such repatriation legislation would result in the decimation of museum collections that contained ethnographic materials. Neither was NAGPRA the first repatriation legislation passed in the United States. The National Museum of the American Indian Act of 1989, which established the National Museum of the American Indian in Washington, DC, provided repatriation legislation aimed specifically at the collections within the various museums within the broader Smithsonian Institution.

NAGPRA required federal agencies and museums to inventory the materials within their collections (either physically within them or those objects on "loan" to other museums or agencies which they maintained "control") to determine those that met the guidelines and definitions for the classes of materials covered by the law. Once those materials which were covered by NAGPRA were identified, the museum, in consultation with the federally recognized Indian tribes who were most likely to be associated with those materials, was then required to develop a plan for returning or keeping the materials. Once these inventories were completed, the tribe most likely to be "culturally affiliated" with the objects was to be given the opportunity to enter into an agreement with the museum for the proper disposition of the objects. Such "disposition" could entail the return of the objects to the tribe, retention of the objects by the museum for the benefit of the tribe, or any other agreement mutually agreed upon by the groups involved.

If materials within the museum's collections could not be identified to a particular group or if more than one group claimed the objects, the regulations implementing NAGPRA provided a list of ten criteria or types of evidence that could be used in helping determine "cultural affiliation." The ten lines of evidence suggested by the regulations include kinship, folklore, oral tradition, and geographical, biological, archaeological, anthropological, linguistic, historical, or other relevant information or expert opinion. Decisions were to be made based on the preponderance of the evidence, not with scientific certainty.

Key Issues/Current Debates

Repatriation of the classes of materials covered by NAGPRA has been ongoing for years, and many Native American tribes and federal agencies and museums have reached workable agreements on the proper disposition of the materials. Most contentious, however, have been classes of artifacts which cannot be easily affiliated with a cultural group because of either the age of the material which makes attribution difficult if not impossible, those materials where the museum or federal agency does not have adequate records to determine general affiliation to either a specific location or time period, materials that are more likely to be affiliated with a tribe that does not have federal recognition (a special government-to-government relationship with the federal government), or other possible reasons for the shared uncertainty.

Museums and federal agencies are allowed to transfer the "culturally unidentifiable human remains" (as well as any other material associated

with them as funerary objects) to tribes from whose lands the materials were excavated, to tribes who once were recognized as the Aboriginal occupants of the land where the materials were removed, or to other tribes who can demonstrate a "reasonable" claim to the materials. In the absence of any tribes that meet these three criteria or if no federally recognized tribes claim the materials, the museum or federal agency can turn control of the objects over to a non-federally recognized tribe, or the museum or agency can actually reinter (rebury) the materials if it wishes.

Scientific and museum organizations have been concerned that this section of the regulations creates situations whereby the scientific value of these materials has been ignored. In written testimony before the US House of Representatives' Committee on Natural Resources Oversight Hearing on the Native American Graves Protection and Repatriation Act on October 7, 2009, Susan Bruning, the Chair of the Society for American Archaeology's Repatriation Committee, responded "stewards of the NAGPRA process [should] seek to carry out their responsibilities in a manner that is respectful of scholarly research and appropriate scientific inquiry as tools that assist in determining 'cultural affiliation' and in understanding aspects of the broader human past" (http://saa.org/Portals/0/SAA/repatriation/BRUNING_TESTIMONY.pdf).

In this regard, the interpretation of the regulations on "culturally unidentifiable human remains" has been thought to be slanted toward repatriation and reburial without the "balanced" approach archaeologists had sought for past repatriation actions. However, in 2015, NAGPRA regulations concerning "unclaimed" materials (43 C.F.R. 10.7) were promulgated which allows a federal agency to transfer materials that have not been claimed by a tribal group to an Indian tribe or Native Hawaiian organization that is not a potential claimant. As a result, the Choctaw and the Chickasaw Nations of Oklahoma have worked together to initiate claims for ancestors in collections in their Aboriginal homelands; the Michigan Anishinaabek Cultural Preservation and Repatriation Alliance (MACPRA) Committee was formed to repatriate unclaimed materials known to have come from within the State of Michigan borders (http://www.macpra.org/mission/).

International Perspectives

Other repatriation actions have occurred throughout the global environment. One such example among many is the volume documenting actions in Australia edited by Paul Turnbull and Michael Pickering (2010) which derives from a conference convened in September of 2005 to examine the status of various relationships with the ongoing process of repatriating Aboriginal Australian ancestral bodily remains. The volume situates the context of global repatriation issues in Canada and Great Britain and the ways that external events have influenced Australian actions. Additionally, there have been recent actions in Japan in relation to the development of the Ainu as a globally recognized Indigenous group and the repatriation of human remains. In 2016, 12 sets of Ainu human remains were returned by Hokkaido University and reburied at a local cemetery after 85 years in an institution, serving as the first repatriation from a Japanese university (Kato 2017: 185). Additional research is underway to regain Ainu human remains from museums in Russia, Australia, and the United States.

Future Directions

In the United States, NAGPRA will continue to play an important role in the relationships between Native American tribes and the federal government and museum environments. New discoveries of human remains as a result of ongoing or new federal construction projects are covered under NAGPRA, and future projects will continue to operate under this legislation's long reach.

Repatriation: Overview

Lynne Goldstein
Consortium for Archaeological Research, Department of Anthropology, Michigan State University, East Lansing, MI, USA

Introduction

In the twenty-first century, most people view the repatriation of human remains and sacred objects as something that is appropriate as well as ethically and morally correct. Tribes and/or appropriate indigenous or religious groups or relatives ask museums or institutions for the return of one or more sacred objects or burials that are historically or culturally related to the group, and the museum or university gives it back. However, this perspective has not always been commonplace, and the process is more complicated than it appears at first.

Most people have little idea of the nature and process of repatriation or the potential associated problems and complications. This is not to say that repatriation is problematic and should not be done, but rather that all parties are obligated to follow a clear and explicit legal process. The biggest difference between repatriation in the twenty-first century and repatriation in the twentieth century is (1) the repatriation of human remains and associated objects is now law in the United States and a number of other countries around the world, and (2) the repatriation of human remains, associated objects, and sacred objects is now widely accepted as something that responsible and ethical institutions do. While most Americans associate repatriation and reburial with Native American remains, this is not always the case, even in the United States.

Definition

The dictionary definition of "repatriation" is not necessarily helpful: "send (someone) back to their own country, or send or bring back to one's own country." Wikipedia defines repatriation similarly:

> Repatriation (from Late Latin *repatriare*) is the process of returning a person back to one's place of origin or citizenship. This includes the process of returning refugees or soldiers to their place of origin following a war. The term may also refer to the process of converting a foreign currency into the currency of one's own country.

The repatriation and reburial of human remains, funerary objects, and sacred objects represent a special case of repatriation. Groups representing indigenous peoples and religious organizations around the world have requested that human remains and sacred objects originally

taken from their respective historical territories be repatriated from museums and other institutions. Sometimes institutions repatriate human remains and items because they agree that they should rightfully be in the possession of the group that is descended from those remains and objects, other times the return is done because the institution acknowledges that the original acquisition was unethical, and still other times the return is based on the requirements of specific laws.

One reason that repatriation – as applied to archaeology and biological anthropology –is not a simple process is because the motivation for these requests is about people in the present and their perception of the past in the present. Repatriation claims are often associated with politics, ethnic identity, and other issues in contemporary society that have, or claim to have, a historical link to the object or human remains. Such motivations in no way make the claim less valid or less appropriate, but the context of the request can be important to understanding the request. Archaeologists, biological anthropologists, and museum directors do not generally approach repatriation from this perspective; they try to contextualize the materials based on science and archaeological and historical knowledge. It is a discussion that has often led to misunderstandings and differences because the parties are focused on different matters. However, since repatriation laws have come into effect, it is a discussion that is happening in many places, and consequently museums are getting better at responding to requests, and indigenous groups are getting better at making their requests (see Colwell 2017 for changing perspectives on these issues). Repatriation is most active in the United States, primarily because repatriation laws have been in effect for the longest period of time. Further, in other parts of the world, laws are not only more recent; they are sometimes unclear applications of previous laws (cf. Sayer 2017).

Please note that although the term "archaeologist" is generally used throughout this entry, the reader should understand that this is a shorthand or simplified way of encompassing people who are archaeologists, biological anthropologists, human osteologists, museum studies scholars, and those in related fields who deal with human remains, grave goods, and sacred or religious objects.

Historical Background

During the 1960s, 1970s, and 1980s, some US institutions listened and responded to repatriation requests from tribes, subsequently returning human remains and sacred objects before there were specific laws in place. However, the passage of two federal laws in the United States – the National Museum of the American Indian Act (NMAIA; 20 United States Code (U.S.C.) 80q et seq.) and the Native American Graves Protection and Repatriation Act (NAGPRA; 25 U.S.C. 3001 et seq.) dramatically and permanently changed the nature and process of repatriation. The effect of this change in process and culture has had international and long-term implications.

Buikstra (2006), Lambert (2012), McKeown (2014), Mihesuah (2000), Trope and Echo-Hawk (1992), and Ubelaker and Grant (1989) provide detailed discussions of the history and some of the problems of repatriation in the United States. During the 1980s, the position held by many institutions, as well as by many national professional organizations, was that the ethics of today supersede those of the past, and museums should consider how to change accordingly. At the basic level, repatriation should be done to living descendants upon request and examination of the claim. As Ubelaker and Grant (1989) note, if a group requested remains where there were no living descendants, that group must demonstrate compelling religious or cultural values that outweigh scientific interests. This position also reflected the position of the Society for American Archaeology (SAA) at the time. However, the SAA increasingly assumed the role of representing the scientific community during the 1980s and their view broadened to some degree.

Since the 1980s, the SAA has been remarkably consistent in their position on repatriation (Lovis et al. 2004). The SAA argued for repatriation, but on a case-by-case basis. Indeed, the SAA

Executive Committee passed an initial resolution in 1983, followed by a revised version in 1986, and a reaffirmed position in 1999. The key points of the SAA position include (1) both native and scientific viewpoints have legitimacy; (2) scientific importance must be considered against the strength of affiliation; (3) implementation of repatriation should be done on a case-by-case basis because of the variability in circumstances and histories; and (4) communication and consultation with affected groups is of critical importance. Since 1986, the SAA (Lovis et al. 2004) has recognized the importance and legitimacy of repatriation and worked actively with Congress to create balanced legislation.

Some native tribes and organizations, archaeologists, and other activists argued that repatriation represented something that was morally and ethically important for the archaeological profession to do, even if archaeology lost access to the remains and artifacts. However, even though several states enacted legislation that in some manner dictated repatriation and/or consultation with native groups, there was no consistent national policy until the 1990s (cf. McKeown 2014).

During the late 1980s, a number of tribes in the United States argued that repatriation of human remains was a human rights issue – that these were human bodies that had to be treated with respect and respect was not possible if the remains were excavated and placed in a museum. Tribes did not see much difference between archaeologists and looters. One incident that angered many (including many archaeologists) happened in Iowa. A cemetery was excavated due to road construction. All of the historic white settlers were immediately moved to a new location and reburied, and the Native American remains were sent to a museum. The lack of consistency and parity and the continuing idea that Native American remains belong in a museum (in part suggesting that this may be because they have no clear descendants) represented the perfect example of what was wrong with archaeology and museums. Ironically, it is likely that in the Iowa case, if archaeologists and biological anthropologists had their way, they would have treated all remains the same but would have studied them all before reburying.

A number of issues and events changed archaeological and other perspectives on repatriation. First, there were several instances, like the aforementioned Iowa case, that led many archaeologists to become increasingly uncomfortable over the idea of study and curation. In the 1980s and early 1990s, the archaeologist who perhaps best personified this position was Larry Zimmerman. In one article, Zimmerman reflects on his experiences and the present and future of archaeology (2000). Zimmerman notes (2000: 294–295) that the reburial issue's trajectory has followed classic syncretism, or a coalescing or reconciliation of differing beliefs. Zimmerman (2000: 295) argues that "the problem has been that the belief system of Western science about the past, through archaeology, had imposed itself on belief systems of indigenous peoples about their pasts and those they consider their ancestors." Because archaeologists had little resistance from these indigenous people over a long period of time, they assumed that these people agreed or did not object. The past 25–30 years has demonstrated that archaeologists were wrong. Public discussion – as represented in various polls and forums – demonstrates that the general public supported the Native American position.

As Buikstra (2006: 395–396) points out, another influence on the relationships between archaeologists and indigenous peoples was the development and impact of postprocessual theories in archaeology in the 1980s and 1990s. This approach to archaeology moved away from being scientific and was humanistic and contextual in nature, with practitioners arguing for multivocality in interpreting the past (cf. Hodder 1985; Shanks and Tilley 1987). Such an approach was certainly more open and welcoming to resolving repatriation disputes, but not everyone agreed with the approach or the benefit for repatriation.

The first US federal law that directly addressed issues of repatriation was the National Museum of the American Indian Act (NMAIA; 20 United States Code (U.S.C.) 80q et seq.), which was signed into law on November 28, 1989. The NMAIA was written and passed primarily to

establish a new national museum dedicated to the history, music, and art of American Indian cultures. The collections of the private Heye Foundation in New York formed the basis of this new museum, to be part of the Smithsonian and built on the national mall in Washington, DC.

The new museum opened in 2004. As a part of the new law, Native Americans had lobbied for a Smithsonian repatriation requirement to be included. In particular, the law affects all collections of Native American, Native Alaskan, and Native Hawaiian human remains and funerary items held by the Smithsonian Institution (although the vast majority of relevant human remains and funerary objects are in the Smithsonian Museum of Natural History, the law affects all of the Smithsonian museums, including the new Museum of the American Indian, American History Museum, etc.). The NMAIA dictates that all designated items are to be inventoried and, where possible, the Smithsonian will determine tribal or descendant origins. When the law was passed, the Smithsonian was estimated to have 19,250 sets of Native American remains (Smithsonian Repatriation Office website). As of December 31, 2010, approximately 29% of this number have been offered for return, and about 20% of the total have actually been repatriated (estimated from Smithsonian Repatriation Office's website – http://anthropology.si.edu/repatriation/faq/index.htm). More remains and items have been offered for repatriation since 2010, but the website has not been recently updated so a more current estimate is not available.

Lambert (2012: 21) makes the point that the NMAIA marks a real "shift in archaeology law from the protection of archaeological resources to the legal acknowledgement of private ownership (or rights of stewardship) by a sector of the American population of a component of the archaeological record."

Legal representatives of appropriate tribes or descendants can request the return of remains and objects; except in special circumstances of direct descent, an individual cannot request return – a person must be approved to represent the tribe. The Smithsonian notifies tribes if they determine an affiliation, but tribes are also encouraged to submit a request for remains to be returned. If there is a disagreement between the Smithsonian and the requesting tribe, the Smithsonian Repatriation Review Committee can examine the case in detail and submit its recommendations to the head of the Smithsonian. The Review Committee is composed of archaeologists, biological anthropologists, tribal representatives, and tribal elders. The tribal representatives on the Committee have one more representative (and therefore one more vote) than the scientific representatives.

One of the most important results of the Smithsonian act is that systematic study of human remains and objects prior to return is a priority, and the law provides funding for a Repatriation Office. As noted by Killion and Molloy (2000), as well as by Ousley et al. (2005), an enormous amount of contextual knowledge and a systematic catalogue have been gained as a result of this law. Data recovered can be used in the future, and data recording has been done in a consistent manner. It is important to realize, however, that the NMAIA *only* affects collections held by the Smithsonian.

The Native American Protection and Repatriation Act was passed on November 16, 1990 (NAGPRA; 25 U.S.C. 3001 et seq.). NAGPRA is a far-reaching law that was crafted as a compromise between Congress, Native Americans, and the scientific community. Although NAGPRA does not apply to the Smithsonian, the Smithsonian has accepted and incorporated the regulations of NAGPRA, and the NMAIA was amended in 1996 to reflect this incorporation of NAGPRA regulations.

NAGPRA has several components:

1. It applies to federally recognized Native American tribes, as well as Native Hawaiian organizations and Alaska native corporations.
2. In addition to human remains, NAGPRA includes the repatriation of associated and unassociated funerary objects (objects clearly part of a burial as well as objects that were likely funerary objects but for which details are unknown), sacred objects (objects required for rituals and ceremonies), and objects of cultural patrimony (objects that are owned by the

group and cannot be owned or sold by an individual).

3. NAGPRA requires museums and federal agencies to identify and inventory human remains and associated funerary objects and also produce a summary of unassociated funerary objects, sacred objects, and items of cultural patrimony by November 16, 1995. These inventories and summaries were distributed to the federal government and appropriate tribes.
4. NAGPRA established tribal ownership of Native American human remains and cultural items recovered from federal and tribal lands after 1990, requiring procedures prior to excavating on such land whether the excavations were inadvertent or intentional.
5. Violation of NAGPRA includes prohibitions against trafficking, sanctions against museums for not meeting deadlines and procedures, and enforcement of the Act by the ability to go to court.

NAGPRA established a Review Committee similar in composition to the Smithsonian's Repatriation Review Committee, with the balance tilted toward Native Americans. NAGPRA also established a grant program for museums, Indian tribes, and Native Hawaiian organizations (although these funds have been very small relative to the need), and the law promulgated regulations to make the law work.

As Lambert (2012: 20) notes:

> These laws reveal significant changes in attitudes concerning the scientific value of archaeological human remains over the course of the 20th century, and illustrate the complexities that can arise when secular and religious ethics collide in the conduct of scientific research.

NAGPRA is important – its passage meant that the federal government was acknowledging that some things in museums were not obtained in a way consistent with modern American ethics, even though the original acquisition may have been legal. Fortunately, NAGPRA was also an impetus for beginning conversations between tribes and the scientific and museum communities. Some tribes and archaeologists had already been talking with each other, but NAGPRA mandated such discussions.

Key Issues and Current Debate

Archaeologists and museums operating in the United States today adhere to federal laws and policies concerning repatriation. While some opposed these laws initially, they now honor the law. More importantly, there has been a significant culture change among the public and among archaeologists and museum professionals, who accept that repatriation is appropriate federal policy. It is important not to minimize this culture change: repatriation is now considered the de facto result of most burial excavation in the United States.

Under NAGPRA and the NMAIA, repatriation does not have a timetable. Except for specific dates by which museums were required to report their holdings, there is no deadline for completion of the repatriation process. This was done deliberately since it was impossible to estimate how long the process would take, and no one wanted to put the burden of a timetable on tribes who were already overwhelmed by the numbers of potentially related remains and artifacts in museums.

A key issue in the passage of NAGPRA was the concept of "cultural affiliation." Cultural affiliation is the basis for decisions about which remains are open to repatriation claims. NAGRPA's definition is "a relationship of shared group identity which can be reasonably traced historically or prehistorically between a present day Indian tribe or Native Hawaiian organization and an identifiable earlier group" (25 USC 3001, Sec. 2[2]). If there is no clear evidence for such a relationship, NAGPRA specifies establishing cultural affiliation based on a "preponderance of the evidence based upon geographical, kinship, biological, archaeological, anthropological, linguistic, folkloric, oral traditional, historical, or other relevant information or expert opinion" (25 U.S.C. 3005, Sec. 7[4]). The preponderance of evidence is a low legal threshold of simply >50%, and all types of evidence are to be treated equally. The notion of cultural affiliation has been problematic in some cases and is the focus for a number of legal and ethical debates about the meaning and intent of the law.

Some think that the so-called Kennewick Man case legally settled the issue of cultural affiliation,

but this is not true (Thomas 2000). Kennewick Man (found in Washington state) was a legal battle over a very ancient skeleton. A group of scientists and a group of citizens (Friends of America's Past) were on one side, and five Native American tribes and bands from the Columbia River Basin were on the other side (technically the case was against the United States). Not only did the skeleton date to a very early time, some biological anthropologists argued that the skeleton had characteristics that were more Caucasoid than Native American in nature. The details of the case can be found in Thomas (2000) and elsewhere. Unfortunately, instead of deciding the case on the basis of cultural affiliation – a finding that might have helped clarify decisions made under NAGPRA – the US Court of Appeals for the Ninth Circuit argued that the federal government had failed to prove that the skeleton was Native American, and therefore it was not subject to NAGPRA. It was a decision that angered Native Americans and also angered many archaeologists because the decision was based on an idea about which Native Americans and archaeologists generally do *not* disagree – both sides would say that ancient remains found in the United States can generally be considered Native American.

Subsequent to the Kennewick decision, attempts were made to amend and/or adapt NAGPRA. Most important for the present discussion was the Department of the Interior's 2007 decision to address the issue of "culturally unidentifiable human remains" (CUHR). This category includes the largest majority of archaeological human remains in the United States. Included are those remains that museums and repositories have not been able to affiliate with a modern tribe or descendant. Following the lines of evidence in the definition of "cultural affiliation" (and outlined above), these are remains for which institutions have not been able to assign an affiliation. For the most part, these remains are those of greater antiquity, with fewer clear ties to the present. Members of the scientific and museum communities had worried about this group of remains from the earliest repatriation discussions because archaeologists and museums were concerned about the impact of repatriation law on the study of prehistory. Some Native American groups were also concerned about the rule from both practical and legal perspectives.

The final rule for culturally unidentifiable human remains (CUHR) was approved in May 2010. The original negotiations involved in crafting NAGPRA had carefully maintained a balance between various interests. The new rule ignores that balance and favors native issues over any scientific interests or concerns; it also does not necessarily give tribes much leeway in how they wish to respond to repatriation. It is likely that this rule could be the focus of future legal challenges.

One issue in the Final CUHR rule focuses on the term "disposition" or the outcome of a repatriation claim. NAGPRA does not mandate the nature or type of disposition for successful repatriation claims, intentionally avoiding the use of the term "reburial." The reason for this avoidance is that a tribe might or might not wish a particular or mandated outcome. While most tribes might wish reburial, if the repatriation decision is that the remains belong to the group, the specifics of the final disposition should be the group's prerogative. The CUHR Final Rule effectively calls for the reburial of all Native American human remains currently in museums and federal repositories, even if evidence for relationship of shared group identity is lacking.

Although many contentious issues remain, current debate in archaeology has moved from the question of whether or not repatriation is right or wrong, to more complicated issues. Colwell-Chanthaphonh and Ferguson (2006) present one aspect of this new direction. Instead of principles and rules of ethics, they promote the idea of virtue ethics. "Instead of beginning with questions of obligations and oughts, Virtue Ethics begins with questions of character, focusing on relationships and the subjectivities of social interaction" (Colwell-Chanthaphonh and Ferguson 2006: 118). They argue that we need to focus on agents and sustained actions, rather than single acts. Effectively, Colwell-Chanthaphonh and Ferguson (2006) argue for a more complex, layered discussion about archaeological practice. They note that archaeologists have a series of unique relationships with multiple interactions, and these interactions have consequences for ethical standpoints.

Sayer (2017) provides examples of the importance of inclusion and consultation. He outlines case studies in which people have protested archaeological excavations of human remains. His examples come from Europe and the United States and primarily focus on historic cemeteries. He notes:

> The past holds meaning for the people of the present, and where projects focus on disenfranchised social and political groups they will desire an involvement in that project, but more specifically in its interpretation. When this has been part of the archaeological project design, investigations have not been hampered by protest but instead have attracted much more positive media interest. . . . (Sayer 2017: Location 1216–1220)

International Perspectives

In their broad discussion of ethics of bioarchaeology, Larsen and Walker (2004: 114) outline three ethical principles for the study of human remains: (1) human remains should be treated with dignity and respect; (2) descendants should have authority to control the disposition of their relatives' remains; and (3) because of the importance of human remains for understanding our common past, human remains need to be preserved when possible so that they are available for scientific research. From the discussions above, it is clear that there may not be universal agreement on these principles.

Canada and Australia share with the United States a basic issue associated with repatriation: the majority of the contested collections derive from minority indigenous populations where treatment of the dead is an important part of broader indigenous rights issues. Most repatriation efforts focus on trying to redress historical wrongs associated with Western colonialism (see DeLeiuen's discussion and summary of the Australian situation in this volume).

Buikstra (2006: 408–409) notes that Canada has no federal legislation similar to NAGPRA, but relationships between First Nations and archaeologists are stronger. Why the difference between countries? First, the Canadian archaeological profession voiced their sympathy with First Nation concerns relatively early, with biological anthropologists practicing in situ analyses and reburials during the 1970s. Canadian bioarchaeologists were collaborating and consulting with First Nations over a decade before US archaeologists, and they did so without being mandated by legislation, producing impressive work with multivocal perspectives. Indeed, there are multiple examples of First Nations requesting osteological analyses and allowing destructive tests. The National Museum of Canada stopped accessioning human remains in the early 1970s. As Buikstra (2006: 412) notes, "Canadian museums, physical anthropologists, and archaeologists appear to favor mediation over litigation in addressing repatriation issues."

Lambert (2012: 25–26) notes that while the United States, Canada, and Australia have seen repatriation on a national scale coming from indigenous populations and issues relating to colonialism, some similar historical situations exist in Argentina, Norway, and South Africa. To date, repatriation efforts in these countries have been limited and generally involve the return of named, historically significant individuals.

In Israel (Nagar 2011: 8), opposition to the excavation of human remains is associated with sites dating to Classical Antiquity and comes from a group of religious Jews who believe that graves of Jewish dead should always remain undisturbed; their political power has been successful in gaining severe restraints on research. Nonetheless, the Israeli Antiquity Authority created and has maintained a human osteological database since 1994; all time periods are included (Nagar 2011).

In Great Britain, considerable dialogue has focused on repatriation and is in part the result of connections to developments in Canada, Australia, and the United States. However, Parker Pearson et al. (2011: 1) provide a recent summary of the issues and concerns. In 2008, "the British government announced that all human remains archaeologically excavated in England and Wales should be reburied after a two-year period of scientific analysis." Not surprisingly, this announcement caused great consternation on the part of museums and archaeologists. It appears that the policy will not be implemented as stated, but Parker Pearson et al. (2011: 3) point out that:

> The weaknesses and contradictions in the legal frameworks that govern archaeology are shocking in many respects, and cannot remain unresolved; archaeologists are pulled hither and thither by property law and planning law, while human remains exist in a peculiar (but ethically and morally appropriate) legal limbo in that they cannot technically be owned.

In sum, outside of Canada and Australia, laws regarding repatriation and reburial are scattered and sometimes under debate; they resemble the issues raised for the United States when there is a similar historical colonial situation. Sayer (2017) provides updated data on these international situations.

Future Directions

Larsen and Walker (2004) discuss the ethics of bioarchaeology and their view of the future. They argue that compromise is the key to reaching an ethical solution to skeletal studies of ancient ancestors. Compromise can be legislated, or it can come about through working together. However, Larsen and Walker (2004: 118) note that this balance achieved through compromise is now endangered with "a perceptible shift in the balance of power toward extremist native perspectives on repatriation." They close their discussion with the comment that "compromise is developed when there is trust between two parties who have invested time and effort in reaching solutions that may not be perfect, but nonetheless attempt to [address] competing interests of different groups" (Larsen and Walker 2004: 118).

An excellent example of a historic cemetery study that was inclusive from the beginning to the end of the project is the Tucson (Arizona) Alameda-Stone cemetery (Heilen 2012). The planned building of a new court complex in downtown Tucson required the discovery and removal of a large historic (1860–1880) multiethnic cemetery. Although project requirements were outlined by court order, the project was successful because of transparency of the work to the affected parties and the development of relationships between the parties. The project developed community-sensitive methods for identifying cultural affinities, as well as addressing a variety of community concerns and requirements. The cemetery included Native American, Hispanic, European, and other groups, representatives of whom were involved in the excavation, analysis, and reburial of the remains and artifacts.

The notion of trust is an important one and will continue to be so in the future. As noted above, Colwell-Chanthaphonh and Ferguson (2006) use the concept of virtue ethics to look to the future without specific reference to NAGPRA. They also discuss the concept of trust and the nature of trust in archaeological practice. They draw on Baier (1994) to outline and discuss "virtue ethics," citing Baier's contention that goodwill is an essential component of trust. Colwell-Chanthaphonh and Ferguson (2006: 122–124) outline the complex web of categories of trust relationships in archaeological practice, noting that there are relationships within categories but also relationships between them. Trust requires goodwill, but each group has to interpret acts of goodwill as benevolent (Colwell-Chanthaphonh and Ferguson (2006: 127). If we wish to develop trust between archaeologists and museums and indigenous groups, all parties must move to a focus on people and actions over time, rather than things and single interactions at one time. Although it takes time to develop and establish trust, the goal has an excellent reward.

In making an international case for resolution of repatriation issues, Sayer (2017: Location 1859–1879) outlines what he calls the Seven Principles of Public Life when dealing with human remains and repatriation issues: "Selflessness, Integrity, Objectivity, Accountability, Openness, Honesty, Leadership." Sayer goes on to note (2017: Location 1879):

> These principles require archaeologists to think beyond the profession, and beyond scholarship. They require independence from the scientific importance of a project while still requiring that individuals and projects are accountable to a scientific community. They ask for openness, accountability to all and objectivity in everything, and if appropriately applied at the beginning of a project they may help to reduce friction, heal hearts and safeguard scientific and public interests for the

future. They require leadership from archaeologists who in that role may become facilitators to access rather than providing boundaries to contact. Most importantly they can be equally applied to research projects and commercial activities and may assist both to fulfill their wider social and academic importance.

Research Laboratory for Archaeology and the History of Art (University of Oxford)

A. Mark Pollard
Research Laboratory for Archaeology and the History of Art, University of Oxford, Oxford, UK

Basic Information

The Research Laboratory for Archaeology and the History of Art (RLAHA) came into being as a result of a dinner in Christ Church in 1949, hosted by Lord Cherwell, involving Teddy Hall, Christopher Hawkes (Professor of European Archaeology), and Stanley Robinson, a keen collector of Greek coins who subsequently gave his collection to the Ashmolean Museum. Lord Cherwell was a physicist and the Director of the Clarendon Laboratory (as well as Chief Scientific Advisor to the wartime and postwar Churchill governments), and Teddy Hall was a D.Phil. student who had recently carried out an X-ray fluorescence examination of the Piltdown cranium and deduced that it had been artificially stained to give the appearance of age. Christopher Hawkes and Teddy retired to Teddy's flat for port and coffee after the dinner, and by morning, the idea of a scientific lab dedicated to archaeological research had been born. Lord Cherwell was instrumental in raising funds, and the whole venture was facilitated by the fact that Teddy declined to take a salary, using the money instead to appoint a Deputy Director. The Lab started in Keble Road in 1953, and the first Deputy Director, Stuart Young, was appointed in 1955. On his return to South Africa, he was replaced by Martin Aitken in 1957.

Major Impact

From the very beginning, the Lab was populated largely by physicists, who were dedicated to developing instruments and techniques for the benefit of archaeology. Teddy's D.Phil. thesis had involved him building the first X-ray fluorescence spectrometer specifically designed for the nondestructive analysis of museum objects. He quickly turned his attention not only to electron microprobes but also, in partnership with Martin, to the development and testing of proton magnetometers for geophysical survey, both on land and underwater. Martin continued his interest in magnetism to develop instruments, initially for dating using direction measurements (requiring in situ samples) and subsequently using intensity measurements. From the 1960s onwards, he also pioneered the use of luminescence measurements on heated pottery as a dating technique (TL), followed in the 1980s by OSL techniques. RLAHA still runs an OSL Laboratory, now jointly run with the School of Geography.

Robert Hedges joined the Lab in 1974, initially as an inorganic analyst, but, increasingly from 1977, with a developing interest in radiocarbon dating by accelerator mass spectrometry (AMS), which had also triggered Teddy's passion for designing and building scientific instruments. The heart of the accelerator is made from a 3-m diameter oil pipeline, which was delivered in 1981. The first dates were published in 1984, and the most publicly notable date, that on the Shroud of Turin, was published in 1988. A replacement accelerator was delivered in 2000, and the Radiocarbon Unit now produces more than 2000 dates a year, including providing a national facility for archaeological radiocarbon dating, jointly supported by NERC and AHRC.

The radiocarbon lab is solely focussed on providing dates for archaeological research, and consequently most of the samples measured are either bone (which makes up the majority) or charcoal. Bone, because of degradation, is one of the most difficult materials to date, requiring scrupulous chemical pretreatment to provide clean endogenous samples for dating. Because of this, the Lab has developed considerable expertise in preparing archaeological bone for analysis, including the recently developed protocols for ultrafiltration, which have resulted in considerable changes to the dates published for the Palaeolithic in Europe. Robert Hedges, once the accelerator was up and running routinely, became increasingly interested in the isotopic study of carbon and nitrogen in bone collagen and has published a number of papers on bone diagenesis as well as a large number of dietary studies using bone isotopes. He has supervised an impressive stream of graduate students in this and related areas.

Both Martin and Teddy retired in 1989, with Teddy being replaced by Prof. Michael Tite, previously at the British Museum, and with Robert Hedges moving in to Martin's position as Deputy Director of the Lab. His place as Director of the Radiocarbon Unit was taken by Christopher Bronk Ramsey, who, as well as running the Unit, has been responsible for writing the Oxcal software, initially for calibrating radiocarbon dates but more recently incorporating Bayesian modelling algorithms which have demonstrably revolutionized yet again the applications of radiocarbon dating to archaeology.

Under Mike Tite, the Lab developed a considerable expertise in the technology of glasses and glazed materials, particularly in Egypt and the Near East. This perhaps marked a change of emphasis from the work in the 1950s and 1960s, away from the development and building of new instruments, to the application of more established scientific techniques to substantial archaeological and technological problems, marking the maturation of the discipline of archaeological science. Mike retired in 2004.

The first volume of the journal *Archaeometry* (a word coined by Christopher Hawkes) was published in 1958, originally subtitled the "Bulletin of the Research Laboratory for Archaeology and the History of Art, Oxford University," but including international contributions from volume 3 onwards. This is still published for Oxford University by Wiley-Blackwell.

In 1962, Martin Aitken organized a day meeting in Oxford for archaeologists who had purchased proton magnetometers to compare notes on applications and review new developments, which became an annual meeting. The scope of these meetings broadened in 1969 to become the "Symposium on Archaeometry and Archaeological Prospection," held in Oxford until 1975. In 1976, with the meeting in Edinburgh, it became the "International Symposium on Archaeometry and Archaeological Prospection" and in 1980 (Paris) the "International Symposium on Archaeometry," which continues to this day as a biannual international conference.

Martin Aitken's contribution to science was recognized by the award of a Fellowship of the Royal Society (FRS) in 1983, and Teddy Hall was awarded an Honorary FBA in 1984. Robert Hedges was awarded the Royal Medal of the Royal Society in 2008.

Basic Information

Address:

Revista de Arqueología Histórica Argentina y Latinoamericana

25 de Mayo 221 3rd floor (1002), Ciudad Autónoma de Buenos Aires, Argentina.

www.arqhistorica.com.ar

rdahayl@gmail.com

Historical archaeology research focused on Argentinean and Latin-American past has experienced an outstanding growth during the last 25 years. Such a development demanded for specialized publications. Despite abundant research carried out within this field in Argentina, peer-reviewed journals did not exist until 10 years ago.

In 2007, a publication with the main goal of gathering Latin-American research results and becoming a regional reference for the specialty was created. The *Revista de Arqueología Histórica Argentina y Latinoamericana*/Journal of Argentine and Latin-American Historical Archaeology (ISSN 1851–3190) was conceived as a peer-reviewed publication of semiannual periodicity. Later, this journal became open access and is currently available at www.arqhistorica.com.ar.

It is mainly dedicated to the publication of original contributions in the field of historical archaeology, as well as in related disciplines (history, historical anthropology, and ethnohistory, among others). The articles consider epistemic, theoretical, and methodological aspects and specific results of Latin-American case studies.

From the very beginning, the publication was also conceived to be a lasting media for the sharing of Latin-American social science beyond the academic community. It sought to raise consciousness regarding aspects such as the value of cultural heritage and the richness of diverse social identities (Fig. 1).

Main Impact

Currently, the journal provides a forum for scientific communication that also attends to high editorial standards. It is supported by a permanent academic committee, national and international reviewers, and the endorsement of numerous academic and research institutions.

As regards the editorial process, all manuscripts are submitted for evaluation, which includes a revision by the editorial committee and a report from two external reviewers of outstanding expertise. The journal is listed in the following databases: Latindex, Anthropological Literature, and REDIB (Red Iberoamerica de Innovación y Conocimiento Científico). Besides, back issues are hosted in JSTOR: www.jstor.org/journal/reviarquhisargla.

Revista de Arqueología Histórica Argentina Y Latinoamericana, Fig. 1 Cover of the first issue of *Revista de Arqueología Histórica Argentina y Latinoamericana*.

During its first decade of existence, the journal published more than 60 articles, as well as reports and book reviews from Argentina, Brazil, Colombia, Chile, Mexico, and Uruguay. Works presented at scientific meetings (*IV Congreso Argentino de Arqueometría*, in 2011; *VII Congreso de Arqueología de la Región Pampeana Argentina*, in 2014; and VI *Congreso Nacional de Arqueología Histórica*, in 2015) have been compiled as dossiers since 2012.

The editors hope that this endeavor will allow for greater interaction within the regional academic community and will help Latin-American scientists to share their accomplishments worldwide.

Basic Biographical Information

Carlos Ribeiro (1813–1882) (Fig. 1) was a pioneer in Portuguese geology and archaeology, being considered as the "Father" of Portuguese prehistoric archaeology. He was born in Lisbon in 1813, among a family of humble condition that could only offer him primary instruction. However, the intense intellectual necessity that he shows, since his youth, takes him to a different destiny than working in a commercial business. It was Filipe Folque (1800–1874), a student of the Royal Academy of Fortification, that lends him several books and helped with secondary school.

Ribeiro, Carlos, Fig. 1 Carlos Ribeiro

Carlos Ribeiro was then ready to get access to superior studies. The Portuguese civil war (1832–1834) leads him to a military career, being promoted to Second Lieutenant in 1840, to Captain in 1851, to Major in 1866, and to Colonel in 1875. But Ribeiro preferred a scientific career instead of a military life. Contact with another artillery officer, José Vitorino Damásio, allowed Ribeiro to acquire knowledge of metallurgy and mines. This provided him the experience to be the Director of the Section of Mines and Technical Department of the Ministry of Public Works, when this ministry was created in 1852. This position allowed Ribeiro to supervise and stimulate mining research in the country. In 1857, the Ministry of Public Works creates the Geological Commission of Portugal, Ribeiro being one of the Directors, together with F. A. Pereira da Costa (1809–1888). The research and professional activities of Ribeiro included the organization of the Geological Chart of Portugal, which he started in 1862.

He was a member of diverse scientific societies from Portugal and other countries, being awarded several times at national and international level.

Carlos Ribeiro was also elected for the Parliament in the legislatures of 1870–1874 and 1880–1881.

Besides his scientific career, he maintained the military status, being retired as General a short time before his death in 1882.

Major Accomplishments

Carlos Ribeiro, together with Nery Delgado (1835–1908), is among the founders of Portuguese Geology. Considering fieldwork as an essential element for geological studies, he inaugurates a tradition in this practice, until then almost nonexistent in Portuguese geological research. Carlos Ribeiro was the first Portuguese geologist to recognize, in a general way, the stratigraphic succession of the lands in the area of Continental Portugal. In 1850, he establishes relations with the British geologist Daniel Sharpe (1806–1856), who lived a few years in Portugal and had published some papers about the geology of the country (Ribeiro 1850). Ribeiro's research allows him to correct some remarks made by Sharpe, what granted him the first international recognition. He kept regular correspondence with the most eminent specialists of the time, especially after meeting them during his trip to several European countries in 1858 (Leitão 2001).

In 1863, he starts his prehistoric studies with the discovery of the Mesolithic shell mounds (kjökkenmöddinger) from Muge, when he was studying the Tertiary lands from the Tagus Valley.

The participation in several international conferences engaged him in the European archaeological movement, mainly in terms of debates around the so-called Portuguese Tertiary Man. This subject, among others, was discussed in 1880 in Lisbon, during the IX International Congress of Prehistoric Anthropology and Archaeology (Ribeiro 1880). Before this event, Carlos Ribeiro had carried out a series of archaeological surveys and archaeological excavations, gathering an excellent collection of prehistoric artifacts for *Comissão Geológica de Portugal* (Geological Commission of Portugal) (Ribeiro 1867, 1871, 1878).

Ribeiro, Carlos, Fig. 2 The bust of Carlos Ribeiro at Museu Geológico (Geological Museum)

In addition to organizing this Conference, Carlos Ribeiro discovered, studied, and published several prehistoric lithic objects that he found at Ota, which he called "sílexes da Ota" (flint from Ota). The pioneering aspects of his studies about prehistoric materials in Portugal gave him the title of "Father" of Portuguese Prehistoric Archaeology (Fig. 2).

In 1878, his geological map of Portugal, presented at the International Exhibition of Paris, was awarded with the silver medal. This map was later reviewed and updated by Nery Delgado and by the Swiss geologist Paul Choffat (1849–1919), which Ribeiro first met during the Exhibition (Choffat 1883).

In 1887, 5 years after his death, several researchers founded at Oporto a scientific association, regarding archaeology and natural sciences, carrying his name in an honorary way (*Sociedade Carlos Ribeiro).* This association started editing a journal that published articles by eminent scholars, such as Paul Choffat and the Portuguese archaeologists José Leite de Vasconcelos and Francisco Martins Sarmento, among other researchers.

Rice: Origins and Development

Dorian Q. Fuller and Cristina Castillo
Institute of Archaeology, University College London, London, UK

Basic Species Information

The genus *Oryza* consists of 24 species, among which two domesticated species are recognized. On the one hand, there is Asian rice, *Oryza sativa;* today one of the most widely grown and productive of world crops, which had its origins in southern and eastern Asia. On the other hand, there is African rice, *Oryza glaberrima*, which is native to and mostly restricted to western Africa (see Fig. 1). Asian rice is conventionally divided into two subspecies, subsp. *japonica* and subsp. *indica*, although more recent genetics suggests that five distinct groups should be recognized within *O. sativa* (Garris et al. 2005): *indica, aus, tropical japonica, temperate japonica*, and *aromatic*. Rice is closely related to bamboos but distantly related to the major cereals maize, wheat, and sorghum (Vaughan 1994). *Oryza sativa* and *O. glaberrima* and their wild progenitors are diploids (2n = 24) with AA genomes. Asian rice is closely related to a wild complex of annual and perennial species, often recognized as *Oryza nivara* and *O. rufipogon*, while African rice is domesticated from the annual *O. barthii*, which in turn is close to perennial *O. longistaminata* (Agnoun et al. 2012).

Rice is cultivated in a wide range of ecological habitats, from dryland to wetland fields, to terraces cut in the slopes of hills and even in deep water up to 4 m. It can grow in altitudes from sea level to 3000 m and is cultivated as far north as 50° in China and as far south as 40° in Argentina (Vaughan 1994; Fuller et al. 2011). Under rainfed conditions, 800 mm of rainfall can be taken as a minimum with higher precipitation preferred. African rice is a traditional staple over major areas of western Africa, while Asian rice is the staple cereal of the most densely populated countries and regions. Many varieties exist, especially in Asian rice, to cater to different tastes. There are sticky and fragrant varieties and colors from white to red and black. The total world production of rice in tonnes is second to maize with China and India being the largest rice producers (FAOSTAT 2012). Asian *Oryza sativa* has been widely grown in western Africa for the past few hundred years, but it remains the case that native *O. glaberrima* tends to be more reliable on poor soils without the application of expensive fertilizers (Richards 1996; Agnoun et al. 2012).

Major Domestication Traits

Rice has been studied in great detail by botanists and geneticists unravelling a complicated history which is still subject to disagreement. Divergent views mainly focus on the origins of domesticated

Rice: Origins and Development, Fig. 1 Map showing the distribution of wild progenitor rices in Asia and Africa, locations of sites with important evidence of African rice, and areas discussed in relation to early rice cultivation in Asia

Rice: Origins and Development, Fig. 2 SEM image of caryopsis of modern rice showing the ridges and profile of small embryo

rice. The single-origins model points towards China as the center of origin, whereas the multiple-origins model indicates *O. sativa japonica* was first domesticated in China and *O. sativa indica* later in India (Fuller et al. 2010). The genetic evidence has established that the two subspecies have different mitochondrial genomes and therefore corroborates two distinct origins, with *indica* derived from an annual *O. nivara*-like ancestor and *japonica* from the perennial *O. rufipogon*. However, those who favor a single origin argue that *indica* was derived from *japonica* rice, with some local gene flow from wild populations (e.g., Molina et al. 2011). What is clear is that hybridization, which may represent intentional breeding, has played an important role in the history of rice as has regional diversification and adaptation (Fuller 2011).

Rice caryopses are one of the most easily recognizable archaeobotanical remains (Fig. 2). Grains are long and laterally compressed. These are characterized by an oblique tip with lengthwise ridges corresponding to the lemma and palea, which had contained the grain. Grain measurements are highly variable, especially in length, but domesticated forms usually have thicker and wider grains than their wild ancestors, making many domesticated types shorter and plumper in contrast to thin wild forms (Murray 2007; Fuller et al. 2010). Other important lines of archaeological evidence include husk patterns, spikelet bases, and phytoliths (Fig. 3). The husk (lemma and palea) has a distinctive and regular reticular pattern. This is often identifiable from husk impressions in ceramics in which rice was used as temper. Advances in archaeobotany have

Rice: Origins and Development, Fig. 3 Illustrations of lines of archaeobotanical evidence for rice in addition to grains, including rice husk, spikelet bases, and two main phytolith morphotypes

also made it possible to distinguish wild from domesticated rice by examining the spikelet base rachilla scars (Fuller et al. 2009). Unlike wild rice, domesticated rice does not naturally disperse its seeds when ripe, making the spikelet base a key line of evidence in tracking the domestication process. Other important lines of archaeological evidence are bulliform phytoliths from rice leaves and double-peaked phytoliths from the husks. Both are certainly diagnostic of *Oryza* and show variation within and between species, but there remain debates about the utility of these phytoliths for tracking the domestication process or separating *indica* versus *japonica* (Fuller et al. 2008, 2010). In Africa, there has been less archaeobotanical research on rice (Murray 2007), with little application so far of spikelet base studies or phytoliths.

Domesticated rice exhibits qualities derived from both its wild species. *O. nivara* is an annual species preferring open habitats but also growing in swampy areas, is daylength insensitive, and self-fertilizing. *O. rufipogon* is a perennial species better adapted to wetlands, is often daylength sensitive, and cross-fertilizing. It is found across a wider geographic range than *O. nivara* including extending to northern Australia and southern China (Vaughan 1994) but previously extending in eastern China northwards towards the Shandong peninsula (Fig. 1; Fuller et al. 2010). *O. sativa* is annual and self-fertilizing like *O. nivara*, though some domesticated rice varieties also grow in deep water and are photosensitive like *O. rufipogon* (Sang and Ge 2007). As rice spread through Asia, hybridization with local wild populations is thought to have provided additional adaptive traits (Fuller 2011). Similar processes are likely in African rice (Richards 1996).

Timing and Tracking Domestication

African rice origins remain obscure. Final Stone Age sites, with ceramics, in the region west of Lake Chad in Nigeria have produced evidence for the gathering and use of wild *Oryza longistaminata* (e.g., Bigga and Kahlheber 2011) by the second millennium BCE, but with no clear

sequence leading to domestication. The earliest domesticated rice finds are grain assemblages from the Iron Age at Dia in the middle Niger River valley in Mali, dating after 800 BCE (Murray 2007). Finds from a few other sites in Mali and elsewhere indicate that African rice was associated with urban sites through first millennium CE and into the Islamic period.

In Asia, five regions are discussed in relation to possible centers of rice cultivation and domestication origins. It is plausible that several of these areas were involved in parallel processes of domestication. The best documented is in the Lower Yangtze where Tianluoshan is representative of a regional sequence of evolutionary change towards domesticated rice. A pre-domestication phase showing morphological change is evident in the sites of Kuahuqaio (6000–5400 BCE), Tianluoshan, and Hemudu (5000–4500 BCE), with agricultural field systems based on domesticated rice emerging by the terminal Majiabang culture (by c. 4000 BCE) at sites such as Caoxieshan and Chodun (Fuller et al. 2008, 2009, 2010). The middle Yangtze region provides some of the earliest evidence for rice use from phytoliths in postglacial cave sites (from c. 16,000 to 15,000 BCE), while cultivation was probably practiced by the time of Bashidang (7000–6000 BCE) with domestication by subsequent phases. Also important in debates is the site of Jiahu on the Huai river (7000–6000 BCE), which lacks clear evidence for rice domestication but has been linked to comparably aged evidence from Baligang some 150 km away on the Han river valley (Zhang and Hung 2013). At Baligang, significant proportions of domesticated spikelet bases occur, suggesting comparability to Tianluoshan or later sites in terms of domestication status. Rice finds from the Houli culture of Shandong are of similar age (Jin et al. 2013) but plausibly wild gathered. While the data from China is rapidly accumulating, they suggest that more than one region may have been involved in parallel development of early rice cultivation and domestication.

By contrast, in India, the search for domestication is focused on the Ganges valley. Combining archaeobotany and genetics suggests that *O. sativa* subsp. *indica* emerged through hybridization from a proto-*indica* that was managed in a morphologically wild state (Fuller et al. 2010; Fuller 2011) with introduced domesticated *japonica* rice, perhaps c. 2000 BCE. The earliest evidence of rice use in the middle Ganges at Lahuradewa has an AMS date of c. 6400 BCE but was plausibly wild gathered or under pre-domestication cultivation. Clear domesticated rice began to become widespread across northern India between 2000 and 1500 BCE. From the Ganges to the Yangtze region, Asian rice cultivation spread to become a major agricultural staple throughout much of monsoon Asia between 1000 and 0 BCE, and it also began to be adopted on a smaller scale as a crop in Mesopotamia (for a review, see Fuller et al. 2010). Asian rice reached eastern Africa during the Swahili period from c. CE 800 (Walshaw 2010), but may not have been added to western African agricultural diversity until the sixteenth century.

Rivers: Environmental Archaeology

Christopher L. Hill
Environmental Studies Program, Boise State University, Boise, ID, USA

Introduction

River environments have played a major role in our understanding of the human past. Humans and other hominids have a long record of using the resources associated with river environments. Whether it is short-term use of a specific resource or long-term settlements, riparian systems have provided valuable habitats. The relationship between humans and river environments has changed over time. Humans have always used the resources found in riverine environments, but over time, they have had an increasing impact on these ecosystems. The environmental archaeology of rivers provides a way to measure changes in riverine ecosystems over time by examining the influence they have had on humans and the effect people have had on these settings. This is done by applying techniques from the natural sciences, in particular the earth sciences and biology, to the interpretation of archaeological sites and their contexts. In addition to providing a natural science approach to interpreting the human past, an understanding of long-term patterns of human and riverine interactions provides a valuable means for developing future sustainable management practices that take into consideration the consequences of climate change and human activities to these important environments. The physical and biologic processes that prevail in river environments can greatly modify patterns of past human activity and therefore have the capacity to transform the archaeological record. The study of river landscapes in archaeology encompasses millions of years of time and every continent inhabited by prehistoric humans.

Definition

The term "environmental archaeology" encompasses the empirical study of the long-term relationship between humans and the physical (abiotic) and biological settings they inhabit. As might be expected, this biophysical contextual approach is rooted in the natural and historical sciences, especially the earth and biological sciences. Because of its emphasis on relationships and interactions, environmental archaeology is connected to ecology, and because it has as a focus human relationships with the environment, it is connected to human ecology. The objective of environmental archaeology is to evaluate the linkages between past ecosystems and people; it examines the relationship between the environment and humans over time. The study of humans and paleoenvironments includes dating methods; abiotic factors such as climate, landforms, sediments, and soils; and biotic components, including vegetation (paleobotany) and animals (paleozoology). Thus, environmental archaeology is commonly divided into three subfields: geoarchaeology, archaeobotany, and zooarchaeology. Some researches further separate the study of the abiotic components of the ecosystem into geoarchaeology and archaeometry. In this approach, geoarchaeology provides a means for examining physical settings, stratigraphic contexts, and site formational processes in contrast to archaeometry, which would include aspects of remote sensing, laboratory techniques for dating, and raw material analysis. Likewise, the study of the remains of plants and animals to interpret past environmental settings or to evaluate their use as resources used by humans may be defined as bioarchaeology. Various scales of time and space can be used in the ecosystem approach to the study of humans and river environments, providing an understanding of the short-term or long-term sequence of events within an archaeological site and its landscape context.

River environments are defined by the presence of flowing water. The flow of water may be perennial (year-round) or seasonal, and it may change in terms of rate of flow on a seasonal basis or over longer intervals of time. These two factors alone have important consequences for humans. For example, if year-round water is present, humans may stay in the vicinity of the river even if there is seasonal availability of particular plant and animal resources. On the other hand, the sporadic availability of water or dramatic changes in water discharge may lead humans to abandon a riparian setting if no resources are available.

There are abiotic and biotic components to a river ecosystem. Besides the flowing water, which is an aquatic habitat, there is the interface between the land and the flowing water known as the riparian (*ripa*, Latin = river bank) habitat. Flowing water is a significant force in the formation of landscapes associated with past and present human activity. It both contributes to the formation of settings or habitats used by people and can modify or transform the archaeological record. Landforms associated with flowing water are termed "alluvial," while sediments deposited by running water are termed "alluvium"; where the landforms are directly attributable to rivers and streams, the term "fluvial" is applied.

Even though particular local riverine environments can be quite variable, they commonly possess similar functional and structural features. This means, although rivers are found in many different settings, there are some basic patterns. Despite their variety, river environments show similar features. An idealized river system will include the channel, a floodplain, and terraces above the floodplain. The channel may be straight, meandering, or braided. Point bars can form in a meandering river which typically will consist of a single winding channel. Lateral movement of the river channel leads to erosion of river banks. Oxbow lakes form where a portion of the channel has been abandoned. Floodplains can include these oxbow lakes as well as levees which are raised areas along the bank of the river. Braided rivers will typically have many intersecting channels within a floodplain. The type of channel can directly affect the ways humans use a riverine environment. Settings

with meandering channels and oxbow lakes may be habitats of high biodiversity or be accessible for human use except during periods of flooding. In contrast, braided streams may be less stable habitats that are used by people on a more sporadic basis.

The rate of flowing water is associated with the amount of water available and the steepness of the terrain. Water flows faster in steep terrain compared to areas where the slope is lower. Larger-size sedimentary particles (including artifacts) are transported in high-energy river contexts, such as channels. Sediments associated with abandoned main channels which form lakes on floodplains are characterized by cross-stratified sands and muds. Especially important for environmental archaeology, channel fills commonly contain plants and mollusk remains and vertebrate bones. Finer-sized sediments are often associated with low-energy overbank deposition, such as on floodplains. Typically, the finest sediments, such as silt and clay, along with lenses of cross-bedded sands can be expected to form overbank floodplain deposits. Terraces, the remnants of former floodplains, can have the same features or they can provide information on previous conditions associated with the river system.

From an archaeological point of view, rivers are dynamic systems. While one part of a river may be dominated by erosion and consequently the destruction of sites, other parts of the river may be locations of burial and consequently the preservation of sites. Thus, one goal of the environmental archaeology of rivers is to account for the basic geomorphic processes that impact individual archaeological sites as well as their surrounding landscapes (e.g., Turnbaugh 1978).

An abrupt movement of a channel belt from one location to another across a floodplain, an *avulsion*, has important implications for the location and preservation of archaeological sites. Dramatic examples of avulsion events are lateral shifts undergone by the Yellow River in China, the Kosi River (a tributary to the Ganges), and the Po River in Italy (Mackey and Bridge 1995). During the late Holocene, over the last 4,000 years, the Yellow River has shifted laterally over 800 km. Over the last 250 years, starting in the 1700s, the Kosi River has shifted about 113 km. The Po River has also seen a series of shifts since about 1000 BCE of about 50 km, with the average avulsion interval of slightly less than 500 years. Some of the youngest avulsions were connected with human actions. Over the last 10,000 years, there have been over 91 avulsion events with the Rhine-Meuse delta with variation over time associated with cross-valley faulting and changes in water and sediment supply (e.g., Stouthamer and Berendsen 2001). These changes in the location of major river channels have serious implications for the location of archaeological sites and the interpretation of settlement patterns.

Biological remains that provide valuable information on environmental settings and resources available for use by people are preserved in river settings. Plant remains are present as macrofossils and also pollen and diatoms, and are also reflected by root casts in soils and sediments. Important invertebrates include arthropods (such as insects and crustaceans) and mollusks (gastropods and bivalves). Vertebrate remains include fish, amphibians, reptiles, and mammals. As with artifacts, these biotic remains can be in primary (in situ, *autochthonous*) or secondary (redeposited, *allochthonous*) context. Evaluating the degree of transportation is critical because it determines what habitat or mix of environments is represented by the fossils. The types of plants and animals change with the terrain and the levels of moisture. Different sub-environments within a river system will have different amounts and varieties of biotic materials; the abundance and diversity will change throughout the riverine system. Thus, there are aquatic resources associated with the channel, marsh and floodplain habitats, and upland habitats. Each can have its own characteristic plants and animals. Fossil remains that are autochthonous will be representative of the local area, while allochthonous assemblages reflect conditions over a much larger area. There are also general biotic patterns associated with riverine habitats from different climate zones. In fact, the same river can have different biotic elements as it passes through different regimes of topography, precipitation, and temperature. Thus, almost by definition, there are a wide variety of studies that are within the scope of the environmental archaeology of rivers.

Historical Background

Studies of archaeological occurrences in riverine settings date back to the beginning of the scientific investigation of the human past. Even before the 1800s, artifacts were found in ancient river sediments. The first recorded Paleolithic hand axes were found in river gravels in the 1690s close to the present location of the King's Cross railway station in London and in the late 1700s at Hoxne in Suffolk. Besides the discovery of Paleolithic artifacts in river gravels, floodplains were key settings for archaeological discoveries. In the late 1700s, Thomas Jefferson directed excavations of an archaeological mound on the floodplain of the South Fork of the Rivanna River, Virginia. Many mounds located in similar floodplain settings have been modified or destroyed over time by the changes in the course of a river or by plowing connected with farming.

During the 1800s, many advances in archaeology were the result of artifacts recovered from riverine settings. Sir Charles Lyell's *Principles of Geology* (published in the early 1830s) examined present-day processes as a way to understand the record of the biotic and abiotic past or as he described it, "the organic as well as inorganic kingdoms of nature." In *Principles*, Lyell restricted the term "alluvium" to sediments transported by rivers and remarked that bones of animals could get buried in alluvium. He cited the channel changes in the Po River of northern Italy since the time of the Iron Age, as well as the consequences of human constructed embankments along the river. Lyell's comparisons spanned the globe; besides the Po River, he compiled information on the action of running water and the erosion and transportation of materials by floods in the Peloponnese of southern Greece and along the Mississippi, Nile, and Ganges Rivers.

Starting in the 1840s, ancient river terraces became important localities that provided evidence for the presence of humans with extinct animals. In France, within river gravels along the Somme River Valley, Boucher de Perthes found stone artifacts and fossils of extinct animals. These observations were subsequently confirmed by the studies of Rigollot in alluvial deposits at St. Acheul, near Amiens. By the late 1850s, the Pleistocene alluvium in the Somme Valley had gained the attention of several prominent British geologists, including Lyell.

Another early example of the study of humans and river environments is found in *Man and Nature* written by George Perkins Marsh and first published in 1864. Marsh was concerned with the changes to the environment caused by human actions. He noted that human activity such as deforestation connected with agriculture led to increased flooding and increased sedimentation. He used accounts from the time of the Romans to document the ways people had modified river systems for irrigation, canals, aqueducts, and reservoirs. The use of land for agriculture was linked to rapid runoff and the increased danger of flooding. Marsh also considered the benefits (flood control, supplies of fresh water) and the costs (loss of farm land, sediment storage, possibility of devastating overflows) of barriers or dams across river channels.

Although many examples of discoveries connected with river environments could be recounted in the history of archaeology, the present-day approach to the environmental archaeology developed during the middle of the 1900s. This approach is exemplified by the contributions of Frederick Zeuner, who held the position of Professor of Environmental Archaeology at the University of London, Institute of Archaeology. In the 1930s, Zeuner used evidence from river deposits to examine the orbital forcing theory for climate change. Zeuner's *The Pleistocene Period* contains extensive descriptions of river terraces and their value for understanding past climates and environments. In this classic text, he evaluates both the geomorphic and paleontologic evidence from ancient river deposits to construct a chronology of the Pleistocene. During the 1950s, an ecological orientation to the study of the archaeological record started to become more prominent. For example, Karl Butzer initiated a long-term program encompassing environmental archaeology with his studies of human interactions with abiotic and biotic processes in the Nile Valley and C. Vance Haynes began his geoarchaeological studies of alluvial sequences in North America.

Key Issues/Current Debates

The key issues connected with the environmental archaeology of rivers center on two questions: to what degree does environmental change impact human activity and to what degree does human activity impact the environment? These issues involve examining the processes of environmental change and the types of environmental resources used by people in river environments. In many cases, the debate involves how the evidence from environmental archaeology should be interpreted. For instance, are the changes seen in a particular riverine setting the results of climate change, tectonic events, or human actions? Evidence from environmental archaeology has also played a critical role in evaluating the changing relationships between humans and the environment. In general, environmental archaeology provides support for the contention that hunter-gatherer (foraging and collecting) human groups have a lower overall impact on river ecosystems compared to agricultural/agrarian and urban populations. The environmental archaeology of rivers contributes to examining questions related to the changing patterns of land use and landscape evolution. For instance, what were the environmental consequences of agriculture in different parts of the world?

Late Paleolithic sites along the edge of the Nile River Valley north of Aswan provide an example of the application of environmental archaeology to study floodplain formation processes, environmental dynamics, and subsistence (Close 1989). Dating from about 21,000 to 12,000 years ago, the sites located at Wadi Kubbaniya were preserved because of the interplay between processes of overbank deposition and blowing sands. The sands often provided a surface on which human activities took place which was then buried by overbank Nile silts from seasonal floods. Besides stone artifacts, many biotic materials were preserved providing a unique view of the seasonal subsistence pattern connected with this river environment. The Nile would flood the dune surfaces around September, and harvesting of fish trapped in ponds between the dunes would happen right after the seasonal flood. Remains of migratory birds suggest possible human use of the river environment during the winter. This time of year would have also been the optimal season for the growth of vegetation along the margins of the floodplain, providing an explanation for the remains of wild cattle and hartebeest. Grinding stones at the sites were used to process tubers during the long interval before and after the onset of the flood. The overall picture is one where humans utilized the diverse resources of the Nile, taking advantage of the seasonal availability of a variety of plants and animals.

A late Holocene archaeological site situated near the border of the United States and Canada in northern Minnesota provides another example where a diverse array of natural science techniques were used to interpret site formation processes and hunter-gather use of riparian resources (Hill et al. 2011). The archaeological site is situated in the active floodplain of the Big Fork River. The stratigraphic sequence shows both lateral migration and aggradation connected with overbank flooding during the last 3,000 years. Human presence begins around 1300 BP and people continued to use the banks of the river as its channel shifted across the floodplain. The floodplain would have been available for human use except when seasonally inundated. By 900 BP, a natural levee was formed along the bank of the river which became a location for human activity. In terms of site formation processes, the artifacts within the site are in primary context, except perhaps for some rearrangement by the overbank flood events that buried the habitation surfaces. Also, artifacts found in point bar deposits appear to have been transported and redeposited and are therefore archaeologically in secondary context. This geomorphic setting was part of an ecosystem that provided fish and aquatic mammal resources. Over time, there was a change from a reliance on spearing sturgeon to taking bottom-feeding fish. Besides the fish, the riparian setting is also reflected by the remains of beaver, porcupine, muskrat, and river otter. The integration of geoarchaeological and zooarchaeological data provides a means to examine both the physical processes of site formation and the biotic resources used by humans along the Big Fork River.

Various natural processes connected with river systems play major roles in the formation of the archaeological record. Tectonics contribute to the evolution of fluvial systems and therefore impact the potential preservation and visibility of sites. The asymmetrical, terraced meander system along the Madison River in southwest Montana is an example (Alexander et al. 1994). This is an instance where there were no major changes in the overall style of channel during the last 10,000 years. It remained a meander belt, but one that was consistently moving towards the tectonically down-tilted area of the valley, leaving a series of abandoned meander belts spanning the Holocene in the up-tilted area. Thus, in this situation, faults caused the tilting of a floodplain across a valley which led to lateral channel migration. In terms of environmental archaeology, the abandoned channels contain a record of late Quaternary environmental change within the river valley.

Studies of the evolution of river systems have been used to determine whether climate change affected human choices about the use of the environment. For instance, a period of settlement abandonment along the Rena River in Norway has been linked to increased flood intensity which caused widespread erosion (Balbo et al. 2010). In some instances, the environmental record of river deposits contains evidence for both climate change and human impact to the surrounding landscape. In China, paleoecological studies of a relict oxbow lake contained evidence of cultivation starting around 5,400 years ago with intensification of agricultural activities about 700 years later (Li et al. 2006). Superimposed on this record of human impact is evidence of climate change that can be correlated with the Medieval Warm Period and the Little Ice Age. An example from Mesoamerica where human action appears to have altered a river system is the study of the Rio Verde Valley in Oaxaca (Joyce and Mueller 1992). From about 400 to 100 BCE, during the Late Formative, flooding and alluviation increased within the river system. This increase appears to have been caused by a change in the pattern of the river; initially, the river was meandering and it changed to a braided stream. In the upper part of the river valley, accelerated erosion and runoff were caused by land clearance connected with farming and settlement. The consequences of these human actions in the upper river valley included increased flooding and river sediment deposition. The flooding and alluviation transformed the meandering stream to a braided stream with high-energy channels, overbank floodplain sediments, and oxbow lakes. This change in the river led to an increase in the agricultural productivity of the lower river valley.

Site formation in alluvial settings is associated with process of erosion, deposition, and post-burial modification. Regardless of whether they are artifacts or ecofacts, objects transported by stream flow are commonly sorted by size, shape, and weight or density. They can be oriented by the current or abraded and broken during transport. They can be transported short or long distances. The longer the transport distance, the higher the amount of expected abrasion and breakage. Quick deposition and burial of biotic materials increase the likelihood of preservation. At site FCW in Bed II at Olduvai Gorge, in Tanzania, artifacts were found in two concentrations that suggested the arrangement was a product of redistribution by river flow. The artifacts appear to have been transported by a flowing river and redeposited on a clay surface and then buried. At the Olduvai site of HWKE-4, the presence of larger sedimentary particles such as sands, pebbles, and gravels indicated a high-energy river environment which would have removed small artifacts (Petraglia and Potts 1994).

Channel settings can be locations for the preservation of macrobotanical remains such as seeds, twigs, logs and leaves, as well as bivalves and vertebrate remains. While mollusks may be in primary context, botanical and vertebrate remains are often transported in channel settings. They may be disarticulated and fractured or abraded, sorted, or preferentially oriented. While providing information on the regional environment, the degree of transport could limit the amount of information provided about the immediate locality. In contrast, channels that become floodplain lakes will contain a mixture of local and

watershed plant pollen contributed through the water, along with the pollen transported through the air. Macrobotanical and animal remains recovered from the fill in abandoned channel lakes on terraces above active floodplains will likely provide more reliable information on local environmental conditions. Floodplains can contain both in situ and redeposited fossils. Materials exposed on the surface can become weathered and damaged and disarticulated by processes like trampling and carnivore activity. Frequent flooding in these settings can help preservation as overbank sediments bury artifacts and ecofacts.

International Perspectives

Studies of past river environments and humans extend beyond the description of a particular site or even a series of sites with a restricted river basin. Historically, there has been much interest in correlating terraces sequences in river valleys with glacial-interglacial climate transitions (Blum and Törnqvist 2000; Mishra et al. 2007; Bridgland and Westaway 2008) or smaller-scale climate events such as the Younger Dryas, the Altithermal, or the Little Ice Age. There is also a global-scale or international dimension to evaluating what natural and social processes are reflected in fluvial deposits containing archaeological materials. While attempts to correlate individual river systems with global-scale processes have long been a part of the study of past rivers and humans, it has become a prominent goal of ongoing research. This can be seen in studies that use paleoenvironmental information to evaluate the risk to present-day populations of floods or the vulnerability of societies to changes in land use or climate (e.g., Arnaud-Fassetta et al. 2010). One very practical application is estimating the long-term frequency of floods in a river system which would provide planners and policy makers with an understanding of long-term environmental patterns. For instance, the last 2,000 years of flood history for the Columbia River in Washington State was evaluated using the stratigraphic sequence at an archaeological site (Chatters and Hoover 1986). The site was on a landform at about the same elevation as the highest historic flood. The stratigraphic sequence consisted mostly of sand and silt along with charcoal, shells, and stone tools. It was determined that there was a high interval of flooding from between CE 1029–1390. Compared to the last 600 years when large floods occurred on average about once every 140 years, during the earlier interval, floods would have been at least three times as common. Thus, the last 600 years has been a period of relative climate stability compared to the interval ending around CE 1390. Examining these types of patterns from a specific riverine site and correlating them to sequences are especially relevant for evaluating broad-scale patterns associated with land use or global climate events.

Future Directions

The potential value of environmental studies of past river systems and their connection with humans has become very apparent. The information from these types of studies is especially relevant for making decisions that affect the sustainability and resilience of these important environments. Some future directions for research include studies linked to landscape evolution, land use, restoration of biodiversity, and landscape management (e.g., Brown 2002; Hudson et al. 2008). In summary, the value of applying natural science techniques and concepts to the archaeological record connected with river environments may ultimately rest on the ways it can contribute to our understanding of the relationships between humans and nature. It can provide decision-makers with a long-term perspective on human land use. Environmental archaeology can also provide a way of examining the ways human actions are a product of both environmental factors and other processes that influence human choices. Thus, a future direction for environmental archaeology may be the application of knowledge regarding the long-term connections between humans and natural systems to broader socially relevant issues of sustainability, resilience, and persistence.

Rock Abrading in South India

R Arjun
School of Business Studies and Social Sciences, CHRIST (Deemed to be University) Bannerghatta Road Campus, Hulimavu, Bangalore, India

Introduction

Rock art is classified into two different types based on the techniques involved in their production. They are pictographs and petroglyphs. Pictographs are drawings by the use of pigments, and petroglyphs are engraving, pecking, and abrading on the rock surface by the use of hard material like pebble hammer or metal tools. The focus of this entry is on few selected sites (Fig. 1) of rock abradings in South India, particularly semiarid environs of Raichur Doab and southern middle Tungabhadra basin (north Karnataka – northwest Andhra Pradesh), where rock abradings in the sites of Neolithic (3000–1200 BC) to Iron Age (1200–300 BC) outnumbering painted images became common. Rock bruising is a popular term known in South India for rock abrading; nomenclature is framed by Robert Bruce Foote (1916: 88) on the initial reporting of the art on granitic boulders along occupational materials of Neolithic culture:

> Rock- bruisings would be the best term by which to describe them. They were, I doubt not, produced by hammering the weathered surface of the rock with stones more or less sharp-pointed, a pastime not infrequently indulged in by the herd boys of the present time whom I have sometimes come upon so occupied. It is true they always ran away when I approached, but I examined their rude hammerings carefully and never found the streak of an iron tool on the freshly bruised surface. (Foote 1916:88)

Rock Abrading in South India, Fig. 1 Sites mentioned in the discussion are semiarid regions of Raichur Doab, Shorapur Doab, and Southern Middle Thungabhadra basin (north Karnataka and northwest Andhra Pradesh). (1) Anandgal, (2) Bilamrayangaudda, (3) Brahmagiri, (4) Kotekal, (5) Maladkal, (6) Maski, (7) Piklihal, (8) Sanganakallu-Kupgal/ Hiregudda/ Birappa rock shelter, (9) Velpumudugu, (10) Vitragal-Devapura/Kupgal, (11) Watgal. (Map prepared by author)

Background

Mr. Hubert Knox was the earliest to bring the rock abrading of South India (from the site of Kupgal) to the scholarly notice (Foote 1916: 87), and Fawcett (1892) produced the first report on it in 1892. Foote (1916) during 1880s–1890s has explored dozens of Neolithic sites with rock

abradings in the Raichur Doab and Southern middle Tungabhadra region of Karnataka. Munn (1934, 1935) revisited and reported rock abradings from many of the sites of Foote that were left unnoticed, for example, the sites of Kotekal and Bilamrayanagudda. His contribution to rock art lays in the fact that he was the first to highlight the pictographs of the region. Allchin (1954, 1960) added to the data of Foote and Munn by recording abradings from the sites like Maski, Piklihal, Kupgal, and Bilamrayanagudda. This should be the beginning and one of the limited systematic recordings of the rock abrading undertaken in this region preceding D.H Gordon (1951), Gordon and Allchin (1955), Allchin and Allchin (1994–1995), Paddayya (1968), Irwin Neumayer (2011), Sundara (1994), Rami Reddy (1971), and Boivin (2004). Among all, Foote (1916), Allchin and Allchin (1994–1995), and Sundara (1994) are specific publications worked on multiple sites of rock abradings and attempted on comparative analysis of the representative images. Whereas, Boivin (2004), Fuller et al. (2007), Blinkhorn et al. (2012), and Korisettar (Korisettar and Prassanna 2014) are site-centered investigations on Sanganakallu-Kupgal complex; for the first time, they analyzed rock abradings in the background of local landscape, society, rituals, and economy. Referring to these publications takes the reader from a basic identification of the rock abradings and the associated archaeological data of many of the sites in South India. In addition, they indicate gradual developments in recording of rock abradings to contextualize on image style and form classification, chronological frameworks, rituals, and social associations emerging during the Neolithic and Iron Age.

Art Scenes and Panels

The subjects of the rock abrading during third to first millennium BC in these regions predominantly were humped cattle (*Bos indicus)*. Other images in lesser number are deer, anthropomorphs, tiger, buffalo, peacock, swan, and elephants. They appear in simple scenes arranged closely to each other or limited to single or double images on a boulder. They fall short of thematic narration unlike the pictographs of India or elsewhere shedding light on the cultural materials and activities of the past societies (Neumayer 2011: 34). Occasionally the panel consists of superimposed and congested images. They are in groups and singles often over the boulder facets overlooking habitational areas or in prominent positions of the hilltops (Allchin and Allchin 1994–1995: 316; Arjun 2018). The panels used on the rock boulders are both easily accessible and at steep slopes challenging artists to draw and investigator to record. For example, in certain locations, one can sit and draw images reaching to a shoulder or eye level of an individual, whereas certain locations are steep and hardly have a space to stand and reach high up to the panel (Arjun 2018). Such steep localities are though challenging to reach, but they contain one of the most appealing images in the sites. They might have resorted to overhanging ropes from the hilltops or vertical chain of humans carrying the artist to reach the panel. Art on such adventurous localities tests the physical fitness of young male (Boivin 2004: 45). However, this should not be resulting in arguing in lieu of "easy accessible locales were of female or age-old productions." There are easily accessible boulder panels bearing large images reaching beyond one's hand stretching extent and as lower as the foot levels. Therefore, gender or age would not have primarily contributed in the art productions at settlement sites as dynamically as the social and landscape factors might have played.

Few scenes take a special note, and the following are selected panels as representative of a larger art assemblage from various Neolithic- Iron Age sites of Raichur Doab and Northern Maidan. Heavy bodied styled humped cattle (*Bos indicus*) imaged on a flat facet granodiorite boulder at the site of Maladkal hilltop (Fig. 2). The cattle images are darkly abraded, thick outlined, bruised infillings, and they are depicted with upward projected 'U shaped' horns and heavy hump (Arjun 2018). Two images on a boulder, horse rider and cattle, are shown as the cattle is being hunted (Fig. 3), and the cattle is responding in a mannered style. These two images should be of different period, probably of late Neolithic and Iron Age.

Rock Abrading in South India, Fig. 2 Humped cattle (*Bos indicus*) depicted in a heavy bodied manner with thick outlines and abraded flillings from Maladkal. (Photo by author in 2016)

Rock Abrading in South India, Fig. 3 Images of horse rider and humped cattle in mannered style from Maladkal. Horse rider with spear or javelin like weapon is later production in date to such humped cattle. (Photo by author in 2016)

Rock Abrading in South India, Fig. 4 Upper two images are cattle in mannered or exaggerated style, and the third one is water buffalo distinguishable through its inward turning horns and forehead projection. The script in the right is Kannada datable to medieval period. Animal images and script abradings differ in color due to the aging, weathering, and patination. (Photo by author in 2016 from Kotekal)

Cattle has abnormally high hump with projected out "V"-shaped horns. The horse and rider are quite naturally depicted, rider holding a spear like weapon. In the site of Kotekal, three images are in a hierarchical dimensionsr (Fig. 4); two of them are cattle and the other is a buffalo, and at the other end of the boulder has a writings in medieval period kannada script (local dialect). This boulder illustrates a very uncommon penal, for the reason that it has depictions of both cattle and buffalo. Interestingly, the cattle are in a diagrammatic or elliptical style, and buffalo is more or less similar to them (the inward turning of the horns with prominently projected head helps in the identification of the buffalo). The cattle images of Velpumudugu are interesting for two reasons. On one panel, two *Bos indicus* cattle breeds are in heavy bodied style with abraded infillings facing each other (Fig. 5a). On the other panel, two cattle are *Bos gaurus* breeds (Fig. 5b) in naturalistic style (breed identification and photos by Dorian Q Fuller). A large panel of Watgal has a group of images superimposed with a combination of subjects like water buffalo, abstract symbols, script, geometric motifs, and anthropomorphs (Fig. 6). Two individuals are anatomically well depicted (Arjun 2018), one male ithyphallic and the other probably a female dancing with upraised arms and leg at Bilamrayanagudda (Fig. 7). At Hiregudda, chains of human images are abraded in a miniature size, running continuously on subsequent boulders, and are accompanied by the other images like elephant peacock, buffalo, and abstract symbols (see Robinson et al. 2008: Figure 5). At the same site, cattle images are arranged in a circular motion with their limbs connected to each other, and in the other stance, single face of the cattle is connected with the bodies of three cattle (see Robinson et al. 2008: Figure 4).

Rock Abradings in Archaeological Association

Fawcett (1892: 150) was the earliest to bring the rock abrading into the archaeological and geographical association, and attributed that the images were produced during the Neolithic times. This

Rock Abrading in South India, Fig. 5 Cattle images of *Bos indicus* (5a) and *Bos gaurus* (5b) from the site of Velpumudugu. (Photo and breed identification by Dorian Q Fuller, taken in 1998)

Rock Abrading in South India, Fig. 6 Images of large sized water buffalo superimposing and accompanied by a set of anthropomorphs, abstract symbols, and early Brahmi script at Watgal. (Photo by author in 2016)

Rock Abrading in South India, Fig. 7 Human figures from Bilamrayanagudda. Male (ithyphallic) and female in dancing postures. (Photo by author in 2016)

assertion was made on the similarity of artifacts found in the Neolithic settlements frequently near the rock abrading localities. The images like elephant gave him a sense of paleoecology, where elephants are not presently a local inhabitant, and perhaps were the spots of earlier environs (Fawcett 1892: 151). However, his assertion on elephant images to be prehistoric depends on the association of animal with the humans; elephant with rider images becomes common in the pictographs of early history and later periods. He also further emphasized on the iconographical differences within the art assemblages and hypothesized on images becoming stylized over the time based on schematization of limbs of the individuals.

Later Allchin (1960) proposed temporal developments in the art forms and styles emphasizing on the evidences of Piklihal and comparatively with the images of Bilamrayanagudda, Maski, and Kupgal. The faunal remains and terracotta figurines of cattle retrieved from the excavations of Piklihal (Allchin 1960) considerably helped him to observe increasing evidences of them in the Neolithic levels, and they were predominant members in the rock art panels. Combination of cultural materials and art suggests at an increasing significance of humped cattle on the advent of agricultural and pastoral economies during the Neolithic and Iron Age (Allchin 1960: 131–133; Allchin and Allchin 1994–1995: 314–315). Neolithic hill settlements frequently exhibit rock abradings and not the medieval and later settlements in the region (Arjun 2018). Therefore, rock abradings and paintings in this region are Neolithic in times and continued down up to early history (Allchin and Allchin 1994–1995: 322). At the end of second millennium and throughout the first millennium BC, art style and subjects were introduced with horses and horse riders carrying metal weaponries in Piklihal (Allchin 1960) and horse riders without any objects in Brahmagiri (Arjun 2018a). This coincides with the beginning of domestication of horse and introduction of metals during the Iron Age in South India.

Allchin and Allchin (1994–1995: 319–320) argued on the forms of humped cattle images beginning from naturalistic to crude depictions during Early Neolithic to later times. Cattle images in naturalistic style are of slender and light bodied images. Crude styles have square or

rectangular body, legs, horns, head tail, and humps that are arbitrarily attached. The other styles among are mannered or exaggerated style, diagrammatic or elliptical style, and heavy bodied style. To a certain extent, iconography of the terracotta figurines of humped cattle retrieved from different excavated layers is indicated at such developments (Allchin 1960). Further, they also indicate the domestication of different cattle breeds (Allchin and Allchin 1994–95: 323). This must be regarded as sequential rather than chronological developments (Arjun 2018). Long and slender *Bos indicus* were wild in the region and were locally domesticated. Heavy body and short horned are a different breed, perhaps brought from somewhere else and are selectively bred. Such images coincide with the horse riders and metal weaponries during the early first millennium BC. Cattle idols in the temples from second half of the first millennium AD are chiseled with swept back curved horns comparable to common forms in a crude styled cattle abradings of Late Prehistoric Period. Such style of images probably represents transitional forms from mannered style and diagrammatic style during the first millennium BC.

Sundara (1994: 37–40) classified the rock abradings native to various geographical regions of Karnataka from his archaeological surveys conducted during 1970s. They are art styles of coastal Western Ghats (engravings only) and semiarid zones (abrading and engravings). In both of these regions, cattle abradings predominate, and the images fall chronologically into Neolithic-Chalcolithic, Iron Age, and Early History. Recent works of Arjun (2018; 2018a; 2018b) disputes with Sundara (1994), on images of protostructural motifs being modern production, and images like tiger and elephants are early historic, and the images of humped cattle, anthropomorphs, and herds of deer belonging to Neolithic-Chalcolithic and Iron Age.

A more recent works later to Sundara and prior to Arjun (2018b), the archaeological examinations at Sanganakallu- Kupgal complex penetrated into the understanding rock abradings in association with ashmounds, botanical and settlement evidences highlighting the ritual concerns (Boivin 2004; Fuller et al. 2007; Robinson et al. 2008; Korisettar and Prasanna 2014). They delineated from accounting on usual image description and turned theoretical over the association of image and sound features at the sites. Mahadevan (1941: 157) and Paddayya (1976) observed that the locations of the rock abradings are often associated with ringing rocks/lithophone in the hillocks of Vitrgal and Kupgal at Shorapur Doab, and this was the very first attempts made in linking rock art image with rock gongs. Their observations were relooked and further examined by Boivin (2004) and advanced with a nomenclature of "South Indian Neolithic soundscapes" based on the arguments that the images at Sanganakallu-Kupgal were made with musical annotations probably during the ritual performance.

Blinkhorn et al. (2012) from the ritual factors turned to contextualizing stone tool manufacturing activities with images production at Sanganakallu- Kupgal. Many of the image localities are found with axe-grinding grooves that were in use during the Late Neolithic and Megalithic. Late Neolithic activities proceed by a ritual of ashmound formation on hilltop and plains (Fuller et al. 2007), and occupation continued with increasing amount of lithic production that must have become a part of it (Blinkhorn et al. 2012: 190).

Robinson et al. (2008) made a fresh approach on the rock art of Birappa and Hiregudda (part of Sanganakallu-Kupgal), where art as well as cultural material activities began since Mesolithic (10000–3000 BC) and Neolithic (3000–1200 BC) and Iron Age (1200–300 BC). Birappa is a rock shelter with multiple layers of superimposed pictographs in which cattle do not appear but animals like deer, antelope, boar, lizards, and hand stencils appeared. A few meters away from Birappa is dyke capped hill of Hiregudda accounting to hundreds of rock abradings with the evidence of Neolithic occupation and stone tool workshops developed comparatively later by 2000 BC (Fuller et al. 2007). Here, indications of single images of cattle were an invention during the earlier phases of Neolithic, and multiple images of herds are taken as a matter of growing community networking and

economy, and the introduction of anthropomorphs was a reinvention during the latter phases of Neolithic. The gradual abandoning of Hiregudda hilltop and occupying its foothill plains, yet must not have avoided the artists to reinvent abradings in the landscapes but continued by adding of anthropomorphs in community dancing and sexual scenes outnumbering cattle or any animals during the Iron Age.

The contextual affiliation of rock art production and other activities in association becomes clearer with the recent studies by the present author at the sites of Bilamrayanagudda, Kotekal, Maladkal, Watgal, Anandgal, and Advibhavi-Rampura, all in Raichur Doab (Arjun 2018). In all these sites, rock-abrading locations are associated with either in combination of evidences such as artificial water pools, rock gongs, axe-grinding grooves, bedrock mortars, and modified terraces. With such combination of activities when geo-referenced to analyze settlement patterning within the site landscapes, the data suggested that abrading localities played a prominent role in holding the societal activities of different economic importance alongside the rituals. Rock-abrading localities with water pools not only indicate at ritual sanctification; rather, it could also be a matter of water becoming an important resource management beyond the ritual life of the people in the semiarid environs. Such developments are not abrupt emergence but could be a gradual process during the Neolithic and Iron Age specifically their focal area being slopes and mid-slopes of the hill sites (Arjun 2018: 265–290; Arjun 2018b).

Future Research Prospects

From the above publications on rock abradings of South India, three phases of research can be marked in Indian Archaeology: first, site findings and reporting; second statistical and attribute analysis of images in the site drawing inferences on their chronology, style, and themes; and, third, interpretation of rock art images in the background of cultural understanding of the sites, geo-referencing art localities with other archaeological remains. Despite of a large number of rock-abrading sites in South India, only few of them are prominently studied to understand the content of the art and scope of images and locations within the sites. Sites such as Sanganakallu-Kupgal, Bilamrayanagudda, Advibhavi-Rampura, Maladkal and Kotekal serve as best case studies that are documented digitally and geo-referenced on the satellite imageries followed by intensive landscape studies. Yet there remain comparative works to develop multiple theories on contextualizing art with socio-politics, economy, chronology, and taphonomic studies. We do not have much time to salvage and initiate detailed studies of the panels on the advent of granite mining in many of the sites in the Southern Deccan. In addition, the gneiss regions of north and central Karnataka have series of dolerite dyke swarms, which are potential to explore rock abradings in non-settlement contexts. The best example is the site of Advibhavi-Rampura in Raichur (Arjun 2018: 269–273). Neolithic people introduced the use of dyke rocks for making of tools, and this makes them to be connected with the dyke swarms. Archaeological explorations at number of dyke swarms could bring to light number of rock-abrading sites, and the absence of occupational evidences at such localities is not a surprise, as the Neolithic people preferred tors and inselberg landscapes than the valleys and plains. We may not expect a completely unique kinds of images adrabed, but their commitment to image production might be different from those at settlement sites.

Sonic production was involved in the making of abrading images, and certain localities of art within the site were not easily accessible unless the artist would have been an athletic male, which is one of the theoretical frameworks in vague (Boivin 2004). Two of these theories are to be tested in the other sites too, especially in the high elevated and low elevated sites like Maladkal and Piklihal. Rock abradings are found on the steep rocky cliffs elevated 60 m from the foothill plains in the case of Maladkal and 20 m at Piklihal. For a note, Piklihal images are not associated with the rock gongs, whereas Maladkal images or any other sites like Bilamrayanagudda

and Sanganakallu-Kupgal do. Such sites with combination of rock art and other archaeological categories associated with rock bruising localities scattered across different elevation of the hills helps on developing site-centred alternative theories, addressing not limited to ritual dynamics but also on the possibility of developing economy and politics surrounding the rock adrading localities.

Cognitive archaeology is yet to see its sunrise in Indian Archaeology (Korisettar 2014). We have much focused on the narration of images by their style and forms but not entering into the debate of what factors that might have triggered them to abrade images followed by the long-existing tradition of pictography across large number of sites particularly during Neolithic and Iron Age. Rock abradings did appear on the advent of Neolithic culture in Southern Deccan and have continued during the Iron Age. How the Neolithic invention must have appealed to the Iron Age populace and what could have made them to succeed Neolithic art is a matter of exclusive inquiry to be initiated. Selection of localities and panels for image production seems to be a factor of careful selection. Were the panel surface modified to any extent for getting a faceted projection should be one of the testable hypotheses. Much of the images are on the faceted nature of the boulders and are often overlooking at the settlement areas. Therefore, how these images appeal from the settlements on the foothill and vice versa are to be recorded with the use of 3D imageries, experimenting on reproduction/replication of images to assert on the amount of labor, skills, and technology required, and also recording on the preservation condition of the panels over the time requires a special attention. These are a few of the research prospects to locate the importance of the rock abradings of South India at a global level.

Rock Art in Namibia

Alma Nankela[1] and Tilman Lenssen-Erz[2]
[1]Archaeology Unit, National Heritage Council of Namibia, Windhoek, Namibia
[2]African Archaeology, University of Cologne, Cologne, Germany

Introduction

Rock art in Namibia is of special interest for research on a global scale because it is particularly rich hunter-gatherer art and it features paintings and engravings (or petroglyphs) in roughly equally shared landscapes that have experienced comparatively little anthropogenic changes since creation of the art. Above all, Namibia is the country where hunter-gatherers lived their traditional way of life in arid landscapes far into the twentieth century and therefore becoming the main reference for forager studies worldwide. However, differently from the Republic of South Africa, none of the extant hunter-gatherer groups in Namibia has recent links to or a cultural memory of the prehistoric art that is generally older than 1000 years. The oldest known African portable art originates from Namibia with the 30,000 years old painted slabs from the so-called Apollo 11 Cave, Southern Namibia (Fig. 2) (Wendt 1976; Vogelsang et al. 2010). While rock art is a country-wide phenomenon where suitable rock is available, western Namibia's region primarily stand out through the density and richness of the art: Dâureb (Brandberg), Erongo mountains, /Ui-//aes (Twyfelfontein) engraving site, declared UNESCO World Heritage Site in 2007, as well as Spitzkoppe Mountains (Fig. 1). To some extent, the concentration of research in these sites was caused by their location in places comparatively easy to reach from the larger cities and because their rather well-known names may have promised a certain prestige.

Definition

Namibia's four outstanding rock art areas constitute characteristic Later Stone Age (LSA) hunter-gatherer rock art environments. However, there is variability in the placement of the artwork in the landscape, in the basic quantitative data and there are variations and idiosyncrasies of two genres of hunter-gatherers rock art tradition (paintings and engravings). Notwithstanding such differences in the quantitative weight of human and animal motifs, abstract symbols or the production of scenes, similarities have been observed in the content of both, paintings and engravings (themes, techniques, stylistic expressions) indicating a broad geographical and temporal continuity of the hunter-gatherer tradition in this life-world.

The **Dâureb** (also Dâures) is a granitic inselberg constituting an extensive mountain oasis on the fringes of the Namib Desert. This circular mountain with a diameter of 30 km rises 2 km above the surrounding desert and savannah areas and harbors about 1000 rock art sites with approximately 50,000 rock paintings, most of which have been published (Pager 1989–2006; Lenssen-Erz 2001; Brandberg Daureb Database n.d.) and over 2700 rock engravings (Gwasira 2011). This density of rock art is owed to the advantageous living conditions for hunter-

Rock Art in Namibia, Fig. 2 One of the several painted slabs from Apollo 11 cave in southern Namibia; with a date of more than 30,000 years Africa's oldest representational work of art showing a therianthropic figure with animal body and human hind legs (max. width 11.2 cm; photo Heinrich-Barth-Institut)

gatherers in this highland. Copious natural cisterns and dense vegetation can be encountered even months after the rainy season, yet no big game. This framework gave reason for the anatomically modern human to settle this area in varying intensity from the Middle Stone Age until the colonial times. The times of the Later Stone Age between 2000 and 4000 years ago are among the phases with most intense activities, and it is also this period when most of the rock art was created (Richter 1991; Breunig 2003).

There is an enormous span with sites containing only a single figure and others with more than 1000. Quite obviously, such a divergence must also go together with differences in use and function. In the number of figures per site the median is 18, accordingly half of the sites have 18 or less figures; but it also means that in this half of the sites

Rock Art in Namibia, Fig. 3 A rich panel from Snake Rock in Hungorob Gorge, Dâureb, showing the inseparable link of rock art with the landscape. (Photo M.T. Erz)

there is only 8% of the entire wealth of art. This indicates a very wide scattering of the art across the landscape (Fig. 3).

On the other hand, the six sites with more than 800 figures make less than 1% of the sites but they harbor almost 12% of the art. Extending these considerations by the inclusion of sites holding more than 200 figures it turns out that more than 40% of the art can be found in only 6% of the sites. These figures show clearly that besides the scattering of the art across the landscape, there is another principle of the art being highly concentrated in a few places. Since rock art is a phenomenon of ritual and religious significance, such concentrations also mean a concentration of powers, supernatural ones that is. These observations are corroborated by further functional analyses of the sites which include features of the natural surroundings as much as archaeological finds and rock art (Lenssen-Erz 2004). The patterns of use suggest a reaction of the people to climatic conditions: the many small sites which could have been used only by a small number of people may have provided shelter during short stays in dry periods. In these times, they had to restrict their group sizes due to scarcity of food and water while keeping up a high mobility since in a small region the limited resources would have been exhausted within short time. The constant preparedness of the people to produce rock art any time even during a short stay at small, inconspicuous places indicates, besides the everyday character of the art, that frequently there arose a necessity to become ritually active (cf. Kinahan 1991: 42). Such high activity is typical for times of crises – which in a region like the Dâureb are likely to be ecological in character (draught). The problems of an ecological crisis could easily become a social crisis as well (competition for resources) to which people reacted by implementing their social and spiritual management tools, the most visible and durable of which are rock paintings. Ethnographic observations among Kalahari hunters show that ritual activities such as healing are significantly intensified when resources are strained (Lee 1979) (Fig. 4).

The two somehow contradictory distribution patterns suggest two basic conclusions: On the one hand, the scattered rock art was a medium of everyday which one could get into contact with anytime "in small doses." Without a special setting and without much ado, the pictures were strewn into the landscape, thus releasing them from a special weight and including them into the everyday. Even in places which were occupied only shortly or where one only passed by, people left behind their pictures.

This pattern is contrasted by the concentration of art in a few "mega-sites," indicating that in some places, which were also suited for large

Rock Art in Namibia, Fig. 4 This extraordinary scene from Ga'aseb Gorge, Dâureb, shows three richly decorated men (shamans?) approaching a giraffe over which a rain shower seems to come down (height of central man 30 cm; photo M.T. Erz)

gatherings, art was celebrated for large crowds. Very likely, these were the occasions where together with the ritual of painting, the entire cultural knowledge with all its rules of conduct between all agents of the physical and metaphysical world was activated. Form and content of communication and behavior would have been strongly regulated through conventions and people would sharpen their awareness that the same kind of art could serve for everyday as well as for the extraordinary, depending on the context.

There may also be an ecological context for the large aggregation sites since they could have been meeting points on special occasions during the rainy season when even with the presence of many people (possibly more than 100) resources would not become scarce.

Rising above 2350 m from the surrounding Namib plains is another principal dome-shaped inselberg, the **Erongo Mountains**, about 100 km ESE of the Dâureb. It has a diameter of 65 km, making the largest and one of key prominent landmarks in central Namibia and one of the key prehistoric rock art areas in Namibia. Its inventory to date stands at more than 108 sites with over 5300 figures (Nankela 2017). However, a large number of rock art collections remain relatively unregistered. Erongo Mountains are located within a transitional zone between the Namib Desert and the savannah woodland; the area supports a rich diversity of flora and fauna. Unlike Dâureb, Spitzkoppe and /Ui-//aes, Erongo receives more than twice the 100 mm annual rainfall of its surrounding Namib Plains as a result of orographic precipitations and other moisture in form of fog. Such advantageous configurations translate to localized microclimates thereby affording favorable living environment for people and animals. Very likely, such resources must have sustained livelihood throughout the years. Consequently, hunting and gathering economic activities may have survived longer into more recent time without being entirely displaced by herder groups. This explains the persistence of archaeological signatures during the later stage of the LSA when some rock art was likely produced (Nankela 2017) (Fig. 5).

Compared to Dâureb and Spitzkoppe Mountains, some farms and areas in Erongo do not exhibit similar patterns of distribution and density which can be attributed to the site use and function. In Omandumba Farms, for instance, the latter indicates that the average number of figures per site stands at 30.4. Consequently, 72% of these sites have between 10 and 49 figures to attest their use. Such sites are widely scattered across the landscape and occupy various topographical locations with very little to no traces of human occupations because they occupy spaces that are not useful for habitation. Furthermore, such sites do

Rock Art in Namibia, Fig. 5 Typical scene with hunters from Omandumba Farm, Erongo. These men carry their hunting gear under their arms and additional bundles on their heads. (Photo A. Nankela)

not necessarily have direct access to reliable water sources. The sites might have functioned as casual hunting blinds, overnight stations for hunters or waymark sites since they are located along the natural travel routes. The characteristics of these sites exhibit the profile features of a typical "Waymark site" (Lenssen-Erz 2004: 145) defined for spatial analyses of Dâureb rock art. Numerically, these sites are dominated by anthropomorphic depictions. Common scenes include hunters bearing hunting equipment (bow, arrows with quiver bags), long sticks and carrying some unidentified objects on their shoulders (which according to local San men can be interpreted as hunted game/meat); very few depictions show social gatherings of people in small bands. Extending these are sites that have between 50 and 169 figures per site, which account for 15% in the repertoire. By character, this defines part of the profile of "Short-term living site," "Long-term living site," "Aggregation Camp," and "Casual ritual site," respectively (Lenssen-Erz 2004). They occupy spacious rock shelters and caves with complex paintings. These sites have strong evidences of human occupations with extensive surface scatter of LSA archaeological artifacts such as lithics, ostrich eggshells, hearths, charcoals, sediments, and beads. Such sites are primarily found at lower topographical locations with direct access to the resources (game and water), with smaller peripheral sites scattered about the same general area. Some of these sites also have good overview of the landscape – which probably meant that the whole territory was under constant surveillance. Such sites might therefore provide security from predators or perhaps rival groups. Very likely these sites functioned as dwelling spaces for long- or short-term stays living. Sites that fit the profile of "Sanctuary, 'hermitage'" account for 13% of the sites with between 1 and 9 figures per panel. These sites are very secluded, highly concentrated, and limited in distribution. They are often isolated on hilltops without neighboring sites and with no useful spaces for habitation – due to their morphology as evidenced by the absence of surface artefacts. Furthermore, they do not have direct access to natural infrastructures. The profile that Nankela (2017: 447–448) assigned to the sites includes "Casual ritual sites" and "Sanctuary, 'hermitage'". Unlike the public displays and greater visibility of artworks in other classes, figures at these sites are often small and placed at inaccessible locations such as ceilings, crevices, and fissures or on boulders where only extremely restricted movements are possible. The sites also depict unusual figures associated with their possible shamanistic functions where hunter-gatherers religious practices were likely carried out, including rain-making, healing, initiations ceremonies for boys and girls, and other shamanistic activities such as out-of-body travel and the spiritual control of game animals. Within this tradition, such shamanistic experiences were perceived, used, and

were expressed in the metaphors that were then transferred to rock art.

Unlike the pattern of usage in Dâureb, which is suggested of partly resulting from people reacting to climatic conditions (Lenssen-Erz 2001; Breunig 2003), the use of many small sites in Omandumba farms, Erongo, may not necessarily translate to such. It could instead be seen that landscape was rather exploited sustainably. Its advantageous configurations meant that Erongo was an affluent area with complex vegetation mosaic for migratory large game and people. Like today, resources (food and water) were probably readily available without people and animals having to compete for it even during dry seasons. Here, very likely people could stay longer and produce rock art only when necessary. This notion is further evidenced by the persistence of hunter-gatherers archaeological signatures about 50 AD. Moreover, Erongo's strategic position could also serve as a corridor between the dry and barren Namib and Savanna grassland during dry seasons for migratory hunter-gatherers bands and large game. This might explain the high density and distribution of archaeological sites towards the southwestern and northwestern sides of the mountain in which directions Spitzkoppe, Dâureb, and /Ui-//aes are oriented as opposed to other areas of the mountain which do not lead to comparable significant forager lands. The high density of such archaeological sites, although known, remains relatively unregistered (Nankela 2017). Erongo's seasonal rivers do not retain water throughout the year, but rainwater disappears beneath the sand of ephemeral rivers. Sometimes this water is readily accessible in shallow, hand-dug wells and complemented by other underground seepages. The existence of permanent springs and a lake may further support its inhabitants during dry seasons which might explain the majority of artworks being strewn across the landscape as opposed to being localized as observed in Dâureb, Spitzkoppe, and /Ui-//aes, whose mega-sites have direct access to scarce localized resources.

Another comparable iconic topographic feature in the central Namib landscape is the **Spitzkoppe** Mountain, rising over the featureless Namib Desert and about 40 km southwest of Erongo Mountains. The complex consists of the Klein Spitzkoppe (1640 m), the Gross Spitzkoppe (1728 m), which lies 15 km to the east, and the Pondok Mountains. Available archaeological record indicates that Spitzkoppe area was inhabited for more than 4000 years. This period coincides with the onset of increasingly arid conditions experienced in the Namib. Paleoclimatic evidence into central Namib and northwestern Namib shows series of rapid aridification events beginning at 3800 BP, which marked a progressive decrease in regional humidity across Southern Africa (Chase et al. 2010: 36–45). Spitzkoppe's archaeological heritage is therefore represented at 65 hunter-gatherers rock painting sites with more than 737 figures, most of which are concentrated around the edges of its granite outcrops (Kinahan 1990). The sites were strategically placed at low topographical configurations because of their direct access to open space and where water and shelter are in convenient proximity. Consequently, such sites may have served as aggregation areas for otherwise dispersed groups of hunter-gatherers occupying these outcrops. Ultimately such aggregation led to the archaeological signatures becoming localized in the area. But also here, in times of ecological crises and diminishing food resources, ritual activities must have intensified (Kinahan 1990) (Fig. 6).

Spitzkoppe rock art is mainly devoted to human and some animal figures. In general, the pattern of use and distribution exhibits similar phenomena as in Dâureb Mountain. Rock art sites are loosely clustered in a number of small groups, with a number of isolated individual sites. The clustered sites sometimes contain one single figure with little or no traces of human occupations to attest their use (Kinahan 1990). Sites with many paintings have complex depictions of artwork related to ritual practices. These clusters surround small water seepages or rock basins where rainwater accumulated (Kinahan 1990). The pattern further reflects both the availability of water resources, suitable shelters among the boulders, and an abundance of food resources (game and edible plants) particularly during and immediately after rain

Rock Art in Namibia, Fig. 6 Another file of men seen at Spitzkoppe Mountain; besides bows also other types of equipment are displayed here with expressive gestures. (Photo A. Nankela)

Rock Art in Namibia, Fig. 7 At /Ui–//aes engravings are scattered widely over a slope with a more or less reliable spring. (Photo M.T.Erz)

seasons. No doubt this pattern also reflects the social spacing of related but separate hunter-gatherer bands (Kinahan 1990). As aridity increased, it evidently led to the seasonal migration of large game and hunter-gatherers to affluent areas that offered favorable conditions such as Erongo in order to cope with diminishing and critical resources. Evidence from the archaeological test excavation in Bushman Paradise rock shelter for instance yielded a radiocarbon dated sequence spanning from the period from 4160 to 1240 years BP (Kinahan 1990). The archaeological deposits contained a well-stratified series of occupation events with hearths, stone artifact assemblages indicative of hunting and gathering strategy, as well as faunal remains such as tortoises, mongooses, birds, rodents, ostrich eggshells, and hunted animals such as springbok. The reduction of big game hunting went together with the production of rock art, possible adjustment of stone tool technologies, as well as the exploitation of plants to supplement diet (Kinahan 1990: 7–8). Such evidence according to Kinahan indicates an early transition from a hunter-gatherer to herding economy. However, evidence for herding is scant with only one depiction that has been addressed as a buffalo or wildebeest (gnu) while Kinahan identified it as cattle.

The fourth key rock art area in northwestern Namibia with the largest concentration of engravings in Southern Africa is Namibia's first World Heritage site, **/Ui-//aes** or **Twyfelfontein** (Fig. 7).

The site is located in a valley flanked by a spring and slopes of sandstones of Etjo, Gai-As and Kuiseb formations while rising above 550 m. Today, the area receives unreliable rainfall pattern with series of ranging temperatures. Its rock art repertoire contains (according to different authors) between 2404 and 5000 figures, most of them engravings and much lesser paintings, (Scherz 1975), with a dominance of animals in form of figures and animal spoors. Human representation is in form of hand and footprints only. The engravings are scattered over an area of several hectares in a sloping terrain with hundreds of sandstone boulders. The majority of engravings are found on open and highly visible rock surfaces (Fig. 8) while others appear to be hidden or intentionally placed at the entrances of natural tunnels in the rock face with restricted movement from one physical space to another (Kinahan and Kinahan 2006: 44–45). The significance of such is not found within the figures themselves but rather in their placement in the landscape, deemed important in ritual practices. Rock paintings on the other hand are concentrated and found exclusively in a few rock shelters that are partly secluded and in hidden locations such as rock crevices and fissures. Such places have been viewed to have "double significance" in that they were likely used by the shaman in solitary preparation for ritual practices and used as points of entry to the supernatural world by medicine man (Kinahan and Kinahan 2006).

Archaeological investigations carried out at numerous rock painting shelters in /Ui-//aes show intensive and repeated human occupations with radiocarbon dates between 3450 and 5850 BP and 370–180 years BP (Wendt 1972; Richter 1991). Such evidence suggests seasonal occupations over the last 5000 years by hunter-gatherer groups. As in most parts of the Namib, this period corresponds to arid conditions in the Namib Desert but the presence of the permanent spring /Ui-//aes, especially during dry periods, meant that water and shelter were found in a convenient location that served as aggregation locale for hunter-gatherer groups and game. The increase of ritual activity during such aggregation would have then culminated into accumulation of rock art within the site.

Key Issues and Current Debates

Contextualizing rock art tradition in the regional archaeological framework is one of the vital components in understanding this complex archaeological material. However, both genres of rock art proved to be difficult, consequently, they are often dated in associations with other archaeological artifacts. Such associations do not necessarily produce the actual age of the artworks, rather the period from which the tradition was likely abandoned. In these cases, it is possible that the artworks could either be older or younger than its

Rock Art in Namibia, Fig. 8 A famous motif at /Ui–//aes is the so-called Dancing Kudu, executed in a rare polishing technique and surrounded by typical geometric motifs that are sometimes associated with waterholes. (Photo M.T. Erz)

associated artifacts. A classic example is from Namibia, is Africa's oldest painting, Apollo 11 *art mobilier* from Southern Namibia, recovered from the Middle Stone Age assemblages. It is possible that the artwork could even be older as demonstrated by the new calibrated data between 31,100 and 32,900 calBP (Vogelsang et al. 2010). Rock engravings are even more difficult because they are mostly found in open-air sites and not in the usual archaeological contexts, which means that they cannot be dated in association with other artefact assemblages.

In order to establish the chronological contexts of rock art, a series of radiocarbon dates collected at several sites within the Dâureb indicate that prehistoric hunter-gatherers settled the mountainous massif between 5000 calBC and 1000 calAD (Breunig 2003: 273). The dating of the rock art itself is a more difficult task. J. Richter correlated radiocarbon dates from painted sites and unpainted sites in northern central Namibia and concluded that the rock art may have flourished in a rather short time period between 3500 and 2000 years BP (Richter 1991: 257). There is corroboration for this time period from archaeological excavations conducted by P. Breunig at several sites within the Dâureb. Most importantly, he excavated an in situ piece of painted rock fallen off the wall. Two radiocarbon dates from charcoal in the relevant archaeological layer yielded ages of 2760 ± 50 (KN-3544) and 2710 ± 60 BP (KN-4117), providing a *terminus ante quem* for the act of painting (Breunig 2003: 83) and supporting the chronology suggested by Richter. Of importance for the understanding of the western Namibian rock art is the fact that the archaeological results from Namibia pre-date the so-called Bantu Expansion (roughly dated to c. 400 AD) that brought pottery and small stock and later iron and cattle to the region.

In Erongo, reliable dates directly linking rock art to sites' occupations have been recorded at a number of important sites. Archaeological excavations at Cymot Shelter, Striped Giraffe shelter, and Davib-Ost Farm near Ameib Farm have produced the earliest LSA occupations in the entire Erongo Mountains from sediments that produced charcoal materials with radiocarbon dates 5740 ± 110 BP and 3790 ± 110 BC. These were supplemented by dates obtained from the Stripped Giraffe shelter between 4590 ± 100 BP and 3080 ± 100 BP, where rock paintings were also found but not recorded. The mid-section of the horizon B of the LSA site of Fackelträger in Omandumba West Farm excavated by Eric Wendt (Wendt 1972: 39; Richter 1991) has also yielded concentration of 360 g of hematite dating 3500–2000 BP as well as a pigment-stained pestle dating 2500 BP and 3000 Cal BP (Freundlich et al. 1980). Such dates were complemented by lithic artifacts directed towards activities such as hunting and tool production recovered from the LSA sequence between 2980 ± 120 BP with most recent dates of 2770 ± 120 BP (Wendt 1972: 39). Another prominent LSA site in Erongo is Leopard Cave, south of the Fackelträger shelter in Omandumba West Farm excavated by David Pleurdeau and other researchers. This excavation yielded significant artifacts, charcoal remains, pigments, grindstones, and pestles dating between 2000 and 3500 Cal BP (Pleurdeau et al. 2012) while test excavations at Rain Cloud Shelter in Omandumba West Farm had also produced vital dates of 2000–2500 Cal BP from charcoal materials, pigments, grindstones, and pestles directly linked to hunter-gatherers rock art production.

The small-scale archaeological excavation at Bushman Paradise in Spitzkoppe had produced radiocarbon-dated sequence spanning from the period from 4160 to 1240 BP (Kinahan 1990). These are said to be indicative of hunting and gathering economy and comparable to the chronological sequence established for Dâureb and Erongo. This site is linked to prehistoric occupation by depictions of figures that show several aspects associated with ritual activities of hunter gatherers.

In /Ui-//aes radiocarbon dates from three excavated sites of Affenfelsen, Zwei Schneider, and Hasenbild rock shelters show variations of Late Stone Age occupation between 3450 ± 40 years BP (KN-I 468) and 5850 ± 70 BP (Pta-2654) (Freundlich et al. 1980). These dates fit in very well in the regional chronology of the Late Stone Age Period occupation. However, since none of the rock paintings and engravings were directly

dated, it is possible that some of the artwork could be older and some might be very much younger.

Future Directions

For the future through the availability of sophisticated GIS tools, rock art research in Namibia has the potential to contribute significantly to the general understanding of spatial organization of rock art and landscape use by prehistoric foragers. This can be based on the dense record of art sites encompassing almost the full number of sites in the respective regions such as in parts of the Erongo or the Dâureb. Particularly for the latter, data for more than 39,000 single figures and more than 600 sites are in open access online (Brandberg-Daureb Database n.d.) besides their full publication in paper (Pager 1989–2006).

With the development and spread of Artificial Intelligence tools as well as crowd sourcing practices, rock art research will learn to harvest large bodies of picture repositories to annotate and tag them, thus making them accessible to new ways of analyses. On the side of the presently prevailing iconographic methods, rock art will thus be analyzed across the board with statistical methods that have little in common with statistical approaches from earlier times.

With the recent expansion of modern analytical techniques using a wide range of instruments such as X-ray fluorescence (XRF), nondestructive *insitu* pXRF analyses, scanning electron microscopy coupled with energy dispersive X-ray spectrometry (SEM-EDS), X-ray diffraction (XRD), particle induced X-ray emission (PIXE), Raman and FTIR spectroscopies (see, for example, Mauran et al. 2019), for elemental analysis and structural characterization of rock art pigments, researchers are able to establish the mineralogical composition used of production of rock paintings tradition. Such studies enable researchers to provide further information about the geographic origin and sources of pigment used, conservation history of rock paintings as well as possible practices employed by artists in producing rock paintings, i.e., mixing with extenders (e.g., ochre with kaolinite), the use of binders (e.g., plant resins, wax, or urine), and/or heat treatment to alter the color of pigments.

Finally, community involvement will make important advances. On the one hand, there is a growing interest in rural communities to claim and foster their links to the cultural heritage, partly in a quest for identity and partly as a sector of economic development. On the other hand, archaeologists begin to employ indigenous knowledge in research, thus acknowledging the depth of insight that knowledge transfer in two directions can provide if members of local communities become part of the research teams (Nankela 2017).

Rock Art in Southern Africa, Regional Difference

Ghilraen Laue
KwaZulu-Natal Museum,
Pietermaritzburg, South Africa
Rock Art Research Institute, University of the Witwatersrand, Witwatersrand, South Africa

Introduction

Before the interpretative approach to San rock art in the 1970s (Lewis-Williams 2002: xiv), a significant interest of amateurs and rock art specialists was the regional differences seen across the southern African subcontinent. After a long hiatus, there has been a renewed interest in regionality (e.g., Hampson et al. 2002; Hampson 2015; Laue 2017). There are three distinct art traditions in southern Africa, the geometric art of the Khoekhoen pastoralists, finger painted art of Bantu-speaking farmers, and the fine line art tradition of the San (Bushman) hunter-gatherers. Considered here is this fine-line San hunter-gatherer tradition. Archaeological and ethnographic evidence points to the wide distribution of San hunter-gatherers and their ancestors throughout southern Africa. Their art is found

painted and engraved across the subcontinent with similarities and distinct differences seen.

It has long been recognized that the art was made by peoples with a similar world view, but regional differences are seen. Although there has been considerable recent work in the subcontinent looking at regional and locally specific traditions (e.g., Blundell 2004), little of this research has looked explicitly at regionality in terms of how to identify regions and what they may mean (see Laue 1999; Hampson et al. 2002 for exceptions).

Definition

Part of the problem with studies into difference has to do with definition. Style has long been used as a way to look at difference but is seldom defined. Many different aspects of the art are considered under the category "style," including the manner of depiction, subject matter, color, and technique. Despite a body of literature problematizing the word "style" (e.g., Boast 1997), the literature on rock art seldom addresses the issues around using this word. This entry takes regional difference to include all aspects of the art that inform on the final "look" of the images in a particular area. These include, but are not limited to technique (engraving vs. painting or finger painting vs. fine line painting), raw material on which the image is painted or engraved, motif or subject choice, differing proportions of image types (e.g., human versus animal), color choices, and subsequent use of the images through superpositioning, repainting, or touching and rubbing. Both the natural constraints of the environment and raw material availability and the cultural constraints of "ways of doing" play a role in how the images are perceived today and divided into different regions.

Historical Background

Some of the earliest work by archaeologists on southern African San rock art concentrated on the similarities and differences of rock art across the subcontinent. Miles Burkitt, a Cambridge prehistorian, spent 3 months travelling around southern Africa viewing archaeological sites. These travels resulted in a publication in 1928 which outlined three distinct rock art painting regions and one engraving region. As with much of the archaeological thought at the time, Burkitt hypothesized that the art was linked to that found in the north, particularly Spain, and had reached the subcontinent through diffusion and migration of people. Differences were thought to correspond to different Stone Tool Industries, the Smithfield, and the Wilton. Burkitt's focus on "typology" (stylistic classification of imagery) and "stratigraphy" (superposition sequences) influenced those that followed (Davis 1990: 280). At the time, elucidation of the meaning of the art was not thought possible, so the only way to study the art was to try and explain the temporal and spatial differences.

Taking the lead from Burkitt, Dorothea Bleek (1932) used her knowledge of the art to expand on the regions proposed by Burkitt. Like Burkitt, many of her described differences were based on motif, color, or subjective descriptions such as the "quantity and quality of the paintings of this Area surpass those in the first area" and that some of the animal depictions are "exquisite specimens of art" (Bleek 1932: 73). In 1941 (updated 1952), Clarence van Riet Lowe compiled an inventory of sites from South Africa and Namibia. He used the information given by magistrates, administrative officers, museums, universities, and schools to map all the known rock art localities. These localities were usually farm names or nature reserves given on the 1:50,000 survey maps. In many cases, there were many sites in each locality (Van Riet Lowe 1952: 2). He divided this area into five separate regions, which, for the first time, was clearly mapped out (Fig. 1). This map forms the basis for the regional maps and studies that followed. In 1970, Jalmer and Ione Rudner published *The Hunter and His Art* which gave an overview of southern African rock art and included an analysis of their eight painted regions and three engraved areas. Although they highlight more regions than van Riet Lowe, their descriptions of regions follow

Rock Art in Southern Africa, Regional Difference, Fig. 1 Map of southern African rock art sites showing van Riet Lowe's five areas. (After van Riet Lowe 1952)

van Riet Lowe. The last person to look at regional difference comparatively across the whole southern African subcontinent was Alex Willcox (1984). While his book covers the whole of Africa, more than a third is devoted to the fine-line hunter-gatherer rock art of southern Africa and focuses on regional differences. The rock art regions proposed for southern Africa (Willcox 1984: 128) largely follow those of the authors previously mentioned with few new insights.

The common theme in all these early attempts to understand regional difference was the use of "style," without any attempt to define what was meant by the term. For the most part, what constituted regional difference was purely impressionistic, and often there was little correspondence between different author's descriptions of the same region. The author's ethnocentric bias and subjectivity are seen in the way the art was described with terms such as "vigorous and attractive" (Burkitt 1928: 131), "characterised by… a certain sense of humour" (Rudner and Rudner 1970: 1790) or being "on the whole more primitive" (Willcox 1984: 181). The principal problem with using "style" to define regions was recognized early on by Burkitt (1928: 132) "the observer . . . will find it far easier to recognize the different styles than to explain their differences," but this did not stop him or others from trying.

To these early researchers, the reason for the differences seen was obvious; different styles equalled different cultural groups. All the authors discussed, seemingly based on Burkitt's (1928) original assessment, claimed that there was an association between the Maloti-Drakensberg art (Fig. 1, area 2) and the Smithfield Stone Tool Industry, and an association between the art of the other areas and the Wilton Stone Tool Industry. In time, the association between the art and the stone

tool cultures became intrinsically bound to identity with the use of terms such as "Smithfield people" (Rudner and Rudner 1970: 180) or "Wilton man" (Willcox 1984: 142). This culture-history approach made the assumption that visual stylistic differences pointed to distinct cultural or ethnic groupings.

In the 1970s, some rock art researchers began to investigate the large body of San ethnography available, and it became clear that contrary to earlier opinions, the overall meaning of the art could be understood (Lewis-Williams 2002). At the heart of San thought lies the idea of a tiered cosmos in which the activities of shamans were all-important to the fundamentals of San life. So it was not surprising to find that the rock art dealt with "similar issues and within the same cosmological framework" (Lewis-Williams 2002: 95). The shamanistic worldview and its reliance on entering a trance state, principally through the central ritual of the trance dance, led researchers to investigate neuropsychological research on altered states of consciousness. Together, the rock art images, San beliefs and rituals and neuropsychology, were threads that were woven together to form a "complex explanatory apparatus" to explain the art (Lewis-Williams 2002: 96).

Over the years, various criticisms have been levelled against use of ethnography in southern African rock art research and the so-called "shamanic explanation." These include the way the ethnography has been used, problems in the collection of the ethnographic data and its reliability, and the problems with using more recent ethnographic information to explain images that could be thousands of years old, leading to shamanic explanations of the art being derided as essentialist and ahistorical. But despite criticisms, the cognitive approach has been extraordinarily successful and still dominates much of southern African rock art studies today. This has meant that the question of regional difference has been largely ignored. However, the old ideas founded on cultural-historical theories retained a tacit currency with the assumption that regional differences pointed to real differences identity.

Realizing the problematic nature of using "style" as a means to assess difference, the question to the few researchers who were interested in regionality became, how else can differences be investigated? In the 1990s, there were two attempts to use quantitative analysis to address this question (Hollmann 1993; Laue 1999). Both studies were constrained by the data collected by earlier researchers as well as the methodological problems of undertaking such a counting exercise. In the late 1960s and early 1970s, there had been a push to make the study of rock art more scientific which resulted in large body of quantitative data for the Maloti-Drakensberg and more limited data set from the Western Cape (Lewis-Williams 2002: 15–28). The quotidian categories used for scenes such as "hunting" and "fighting" spoke to the understanding of the art at the time; it was seen as a record of daily life and the shamanic elements of the art were not properly recorded (Lewis-Williams 2002: 20). The later quantitative studies therefore opted to only use the more basic data collected, such as animal types, male to female ratios and color used. Distinct differences were found between the areas studied and the earlier quantitative data from the Western Cape and Maloti-Drakensberg, but there was little attempt to investigate what these differences could mean (Hollmann 1993; Laue 1999). Quantitative analysis could point to differences in what was painted in various "regions" but could not explain what these differences meant in terms of the people who made the art.

A more recent attempt to explicitly look at regionality in southern African rock art recommend that, in order to avoid the tricky topic of style, motif should be the only factor investigated (Hampson 2015). Jamie Hampson (2015) suggests an approach to the investigation of regional difference by looking at the presence or absence of imagery. Three broad categories are suggested "1. Widely distributed rock art motifs; 2. Regional rock art motifs; and 3. Extremely rare or unique rock art motifs" (Hampson 2015: 90). Hampson uses this method to interrogate the imagery found in the Mpumalanga Province, South Africa, and compares the imagery to other areas in the

subcontinent. His analysis shows that while the art of Mpumalanga remains within a broad shamanic framework, there are differences in the motifs emphasized. He does not attempt to understand why we see these difference, instead concluding "[e]xactly what those regional emphases may signify is, at present, impossible to say" (Hampson 2015: 112). This approach still does not get down to solving the questions of how to define regions and what they may mean. There is also a problem of bias; how does one decide on which motifs to consider necessary in the analysis.

Which motifs are looked at will influence what a region will look like, the spread of so-called "regional motifs" are unlikely to all have the same boundaries. In the case of "widely distributed rock art motifs," it is difficult not to take into account their manner of depiction. Eland are the most common, identifiable, antelope painted in both the Maloti-Drakensberg (Fig. 2) and the southern Cape of South Africa (Fig. 3), but the way they are painted is very different. But even looking at manner of depiction has its problems, while only one image of a shaded polychrome

Rock Art in Southern Africa, Regional Difference, Fig. 2 Polychrome eland from the Maloti-Drakensberg, north Eastern Cape Province, South Africa. (Photo credit: Rock Art Research Institute)

Rock Art in Southern Africa, Regional Difference, Fig. 3 Bichrome eland from the Western Cape Province, South Africa. (Photo credit: Rock Art Research Institute)

Rock Art in Southern Africa, Regional Difference, Fig. 4 Swift-tailed therianthropes from the southern Cape, South Africa. (After Hollmann 2005)

eland is known from the southern Cape, there are many monochrome and bichrome eland from the Maloti-Drakensberg which are similar to those of the southern Cape. In the case of more unusual images which have a limited distribution, the argument could be made for information exchange across that region. An example is the swift-tailed images found in a limited area, approximately 600 km by 40 km, of the southern Cape (Hollmann 2005). These unusual therianthropic figures (Fig. 4) have a human head and bird body. The similarities in the way the images are painted over this large area argue against independent origins in many locals but rather point to contact between painters across this subregion. More widely spread motifs point to the known similarity in hunter-gatherer belief systems across the subcontinent. If motif is the only factor considered, then the result is motif regions which ignore all other factors that contribute to the look of the art. Motif should aspect of the art that is investigated when looking at regional difference but should not be the only consideration.

Key Issues

There are many challenges to the study of regional difference in southern African hunter-gatherer rock art. Below are some key issues which need to be considered:

- The dating of southern African rock art sites is still in its infancy. To date, only a handful of images have been directly dated (Bonneau et al. 2017). The oldest date, obtained so far, for parietal art in southern Africa comes from Botswana with a date of 5723–4420 cal BP. Dates from western Lesotho are given as 2326–965 cal BP, while dates from the Maclear region, in the north-Eastern Cape, South Africa are given as 2998–2381 cal BP (Bonneau et al. 2017: 675). All these dates fall in the mid to late Holocene, but there are indications from the excavation record that hunter-gatherer rock art in southern Africa has a much greater time depth. The oldest dated painted stones were excavated from the Apollo 11 Shelter in

Namibia and date to at least 26,000 years ago (Lewis-Williams 1984). Although research indicates that at least some of symbolism seen in the art has a great time depth (Lewis-Williams 1984), one cannot expect that the way people made the art and the choice of motifs stayed static through time. A lack of dates means that there will be an inevitable flattening of the diachronic and synchronic elements used to investigate regional difference. However, this does not mean that regionality cannot be studied, but instead, we are likely to see broad regional trends rather than micro-regional differences.

- Motif is only one factor of many that needs to be considered when investigating difference. Quantitative analysis has shown that there are differences in the percentages of different motifs in different parts of the subcontinent. For example, female figures are more frequently painted in the Western Cape compared to the Drakensberg and southern Cape (Laue 2017: Fig. 16). The percentages of animals as compared to anthropomorphic figures in the paintings also differs between different rock art areas; in the Drakensberg, human figures only slightly out-number animal images, while in the southern and Western Cape, there are almost twice as many animal figures (Laue 2017: Fig. 25). Beyond motif, how the images are painted and how they "look" is another a critical component to consider. An example is the way that human figures are painted in different areas. In the Groot Winterhoek Mountains of the southern Cape, just over 50% of the humans are painted with hook heads compared to 18% in a study in the Drakensberg (Laue 2017: 160).
- The way the art was made, often termed "style," is a crucial factor in many of the differences noted between different areas (e.g., Figs. 1 and 2).
- Beyond simplistic ideas relating difference to ethnic or linguistic groups, there is seldom consideration given to what regional differences tell us about people of the past.
- There are still large areas of southern Africa where little or no survey work has been done. Where intensive work has been undertaken, the researchers often focus on specific aspects of the imagery or a particular motif rather than giving a more general characterization of the art needed for regional comparison.
- Geology and environmental differences are often ignored by those trying to understand difference. These natural constraints affect both what is painted (e.g., if eland do not commonly occur in a specific area, they are unlikely to be painted) and how it looks when painted. Differing geological substrates influence the placement of images as well as how the end product is perceived and how it weathers over time.

International Perspectives

Studies in regional difference in rock art, a primary focus of study in other parts of the world, encounter similar problems to those faced in southern Africa. There is little published on theoretical and methodological approaches to difference. Instead, "stylistic" differences are analyzed and often pinned to linguistic differences (e.g., Taçon 1993: 118).

With this reliance on the concept of style in much of world rock art studies, translation of these ways of looking at regional difference into a southern Africa situation is not easy. More recent studies appreciate that in order to understand regional differences and similarities, it is crucial to understand the "networks of relationships in which the rock art in embedded," but there is still a reliance on "style" as a means of classification (Brady and Bradley 2014: 376). In many cases, it is easier to justify the use of the term style, as often the cultural breaks are much more apparent. It is analogous to the differences seen between San rock art and farmer art in the Limpopo Province of South Africa. The former is a fine line art related to shamanism and beliefs about the spirit world, while the latter is a finger painted art, usually white, related to other practices such as initiation or protest (Smith and van Schalkwyk 2002). Although there are overlaps in motif, the manner of depiction is so

different that there is no confusing the two. Very little of the regional work in Australia and North America seeks to look at regional difference between areas of art which are similar in manner of depiction and have been shown to have been produced by people with very similar worldviews, as is seen in southern African San art (cf. Taçon 1993: 118).

Future Directions

This entry may seem to have painted a bleak picture of the state of research into regional difference in southern African rock art, but there is cause for optimism. Two main questions need to be answered when investigating regional difference. First, there are distinct differences between areas, but how can we record these differences without resorting to the tricky term "style"? Second, what do these differences mean?

One suggestion (Fiore 2007; Laue 2019) is that we take a more holistic approach to investigate difference. Using the idea of the *chaine opératoire* we can look at the art-making process from production to consumption. Each step along the way can be examined and thus, the differences due to natural constraints (e.g., geology, environment) can be separated from the cultural "choices" made by the painters. Further, each step or "choice" can be isolated, and similarities and differences compared. Take, for example, the two eland in Figs. 2 and 3; the difference is immediately apparent. We could say that the one is more naturalistic and the other more stylized or even worse one is more aesthetically pleasing than the other, but this does not give us a way to understand their difference. Using the method proposed above all of the following would be taken into account: differences in geology, color, technique (shading vs. no shading), details such as horns and finally how differential weathering has affected the images. Where possible, it is also important to consider the age of the paintings as older images may have lost many of their details over time. When moving beyond single images, motif "choices" could also be considered as could superpositioning. Together all these factors influence differences in the "look" of the images and differences between different regions.

Style, the presence/absence of motifs, or any other method of assessing difference does give clues to why regionality exists. Research into African farmer archaeology has challenged the view that cultures have discrete boundaries which indicate ethnic or linguistic units. Instead, the landscape can be viewed as a series of many overlapping communities of practice (Stahl 2009: 250). We are able to look at "ways of doing" without resorting to culture-history modes of thought using the concept of "communities of practice." "Communities of practice are groups of people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise in this area by interacting on an ongoing basis" (Wenger et al. 2002: 4). Although rock art in hunter-gatherer society fulfils a different function to pottery in farmer society, exploring the formation of communities of practice through the practice of learning and knowledge transfer can help shed light onto the differences and similarities we see in the rock art across space (Laue 2019). There are two benefits to using the concept of "communities of practice." The first is that it is the practice of making the object that is important rather than the "style" of the finished product, which gives us a way of investigating rock art which avoids the problematic use of "style." Secondly, this theoretical view lets us move away from the ideas that relate material culture to ethnicity or identity and instead look at difference as a function of different practices over varying distances in space.

Rock Art of Siberia: Baikal and Transbaikal Regions

Irina Ponomareva
School of Humanities, Languages and Social Science, Griffith University,
Gold Coast, QLD, Australia

Introduction

Siberia is an extensive geographical region, and it has a rich body of rock art. This entry is focused on two interrelated large rock art provinces: the Baikal and Transbaikal regions. It starts with an outline of timeline and geography, continues with the history of rock art scholarship, and then is followed by a review of rock art traditions and styles in chronological order with a discussion of relevant issues, debates, and future directions.

Definition

As in many parts of the world, in Siberia, the issue of the earliest rock art is problematic, and established traditions, groups, and styles were related to the periods of Neolithic, Bronze Age, Early Iron Age, and Middle Ages. The

Rock Art of Siberia: Baikal and Transbaikal Regions, Fig. 1 Sites mentioned in the text. 1, Manzya; 2, Ushkaniy island; 3, Dolgiy Rapids; 4, Second Kamenny Island; 5, Shishkino; 6, Tal'ma; 7, Sagan-Zaba; 8, Sakhyurte; 9, Elgazur I; 10, Aya bay; 11, Nutgei; 12, Orso; 13, Sarbadui; 14, Baga-Zarya; 15, Mondogor-Khabsagai; 16, Khaisagar; 17, Maly Gutai; 18, Ust'-Menza I; 19, Shaman-Gora; 20, Gol-Tologoi; 21, Zal'tira; 22, Bain-Khara Angirskaya; 23, Khotogoi-Khabsagai; 24, Mukhorshibir (Onokhoiskaya); 25, Butikha; 26, Ust'-Tsoron; 27, Byrka; 28, Urulyungui I; 29, Srendeshaikino; 30, Srednyaya Nyukzha; 31, Nyukzha; 32, Mongol'dzhin (Mongolzhon)

populations of the Baikal and Transbaikal regions shared many cultural trends and actively engaged in the cultural processes of Central, Northeast, and East Asia. As it is conventionally accepted, the Neolithic Age in Siberia starts with the adoption of pottery, and the general periodization for the Baikal region can be outlined as the following:

Early Neolithic: 8000/7500–5500 BP
Late Neolithic: 5500–4500/3800 BP
Bronze Age: 4500/3800–2700 BP
Early Iron Age: seventh century BC to fourth century AD
Middle Ages: fifth to sixteenth centuries AD

There are different ways for the regional division of Siberia depending on the context. In this entry, regions are defined in order to better describe rock art provinces. The Baikal region is understood as an area to the west from Lake Baikal, which includes the western coast of Lake Baikal and southern sections of the Angara and Lena River basins. The Transbaikal region, or Transbaikalia, is understood as an area to the east from Lake Baikal and includes two Russian federal subjects, the Republic of Buryatia, conventionally referred to as Western Transbaikalia, and Zabaykalsky Krai, referred to as Eastern Transbaikalia. Some sites discussed in the entry are located in the adjacent federal subject of Amurskaya oblast, which is not traditionally considered as a part of Transbaikalia (Fig. 1).

Historical Background

The history of rock art research in Siberia started back in the eighteenth century, and the rock art

sites of Baikal and Transbaikal regions were among the first to be mentioned. These are the petroglyphs of the Angara River surveyed by Daniel Gottlieb Messerschmidt in the 1720s and by Johann Georg Gmelin a decade later. Gmelin also discovered and documented the Shishkino rock art site. In addition, some rock art sites at the Temnik and Dzhida Rivers, which are tributaries of the Selenga River, were mentioned by Friedrich Müller, the leader of the academic group of the Great Northern Expedition (1733–1743) (Okladnikov 1959, 1966; Okladnikov and Zaporozhskaya 1969).

In the nineteenth–early twentieth centuries, the aggregation of knowledge about East Siberian rock art accelerated. A number of rock art sites were discovered in the Angara River basin and surveyed by several explorers, namely, by geologist Yakovlev (1810), by a Polish convict and self-educated archaeologist Nikolai Witkowsky (1882), by Plaskovitsky (1888), by another convict Dmitri Klements (1889), and by archaeologist and archivist Mikhail P. Ovchinnikov (1916). The rock art sites on the coast of Lake Baikal were studied by N.N. Agapitov (1881), by Timofey I. Savenkov (1913), and by Berngard Petri (the 1910s–early 1920s). The latter was an influential archaeologist and anthropologist who, while working at the Irkutsk University, trained such well-known researchers as Alexey P. Okladnikov and Mikhail M. Gerasimov (Okladnikov 1966, 1974). Some brief reviews of the Baikal and Transbaikal rock art were published by Pavel P. Khoroshikh (Okladnikov and Zaporozhskaya 1969).

During this period, several rock art sites were examined and reported in Transbaikalia, such as Khotogoi-Khabsagai in the Uda River basin by Finnish ethnologist and philologist Matthias A. Castrén (1840) and by D.P. Davydov (1856), Mongol'ddzhin in the Eastern Sayan Mountains by Peter A. Kropotkin (1865), a rock art site at the mouth of the Temnik River by A.P. Mostits (1895), Khaisagar and Maly Gutay in the Khilok River basin by N.V. Kirillov (1897), and the rock art sites of Mukhorshibir, Gol-Tologoi, and Zal'tira by V.V. Popov (1925, 1927) (Okladnikov and Zaporozhskaya 1969, 1970, 13).

In the 1930s, the rock art sites of the Uda River basin were examined by G.P. Sergeev and E.R. Rygdylon. They suggested a relationship between rock art panels and burial grounds which were often found nearby, although Sergeev associated them with those belonging to the slab grave culture (the Late Bronze Age–the Early Iron Age) and Rygdylon – with those of the late nomadic culture (the Late Middle Ages). Information from Rygdylon's and Sergeev's field reports of 1934–1935 was later incorporated in Okladnikov's two-volume monograph.

A major advance in the rock art studies of Siberia was brought by Alexey Okladnikov. His explorations were so vast and intense that they included the whole of Siberia and Central Asia and all periods of human history. Concerning only the Baikal and Transbaikal regions, Okladnikov covered the following. In 1927, he reported a rock art site near the village Fofanovo. In 1929, Okladnikov rediscovered the Shishkino rock art site, which was studied again in 1941, 1947, and 1957 (Okladnikov 1959; Okladnikov and Zaporozhskaya 1959). In the 1940s, he explored the basin of the Lena River from the source to the mouth. The result was a fundamental work on the prehistory of Yakutia in which the rock art of the Upper and Middle Lena River basins was considered along with other archaeological data, although the rock art materials were completely published 20 years later (Okladnikov and Zaporozhskaya 1972; Okladnikov 1977). During 1947–1958, the systematic research of Transbaikal rock art was conducted by the Buryat-Mongol archaeological expedition, which was led by Okladnikov (Okladnikov and Zaporozhskaya 1969, 1970). He also recorded rock art sites of the Angara River during 1934–1937 and 1951–1959 (Okladnikov 1966). In 1968, 1971, and during 1973–1974, Okladnikov examined rock art sites at the Lake Baikal in the Sagan-Zaba and Aya bays (Okladnikov 1974) and, in 1976, discovered new rock art sites in the Barguzin valley (Okladnikov et al. 1980). The result of his rock

art research was more than 20 monographs containing an enormous number of tables with drawings. Okladnikov also wrote a popular science book on rock art, *The Deer with Golden Antlers*, which inspired many young archaeologists.

Okladnikov significantly advanced rock art research by bringing it into a prominent position within the broader field of archaeology and by providing the first reliable chronology of Siberian rock art, which was originally developed based on the materials of the Shishkino rock art site (Okladnikov and Zaporozhskaya 1959). He then applied this chronological framework to other rock art provinces (Okladnikov 1966; Okladnikov and Zaporozhskaya 1972). Okladnikov was the first Soviet archaeologist who used analogous depictions on artifacts from archaeological context to date rock images. Although some of his presumptions were not valid and some of his conclusions have been debated (Mel'nikova et al. 2011), in general, Okladnikov's chronological scheme is still relevant. Okladnikov also collected all available ethnographic data to uncover the meaning of prehistoric pictures, even though this was done within the framework of Marxist theory, predominant at the time in Soviet humanities.

Okladnikov was not the only one who explored rock art in East Siberia in the Soviet period. In the Transbaikal region, in the 1940s–1960s, the exploration of rock art and the search for interpretations were conducted by the head (1946–1978) of the Kyakhtinsk Local History Museum, Rodion F. Tugutov, and local researcher Galdan L. Lenkhoboev. They also participated in Okladnikov's Buryat-Mongol archaeological expedition and provided him with information on rock art sites (Okladnikov and Zaporozhskaya 1969).

In the 1970s–1980s in East Siberia, Okladnikov's exploration was continued by his disciples, and one of them was Alexander I. Mazin, who recorded many rock art sites in the Eastern Transbaikal region, Southern Yakutia, and Upper Amur basin. Mazin paid a lot of attention to the excavations under rock art panels aiming to relate the pictures with the datable cultural remains and to investigate the religious role of the sites. Although the relationship between the pictures on rocks and the culture deposits underneath is not obvious, Mazin's presumption about religious actions allowed him to correlate groups of similar pictures defined on a panel (stylistically or made by the paint of the same color) with stratified culture deposits (Mazin 1986, 1994).

The study of Transbaikal rock art was continued in the 1970s by Alexey V. Tivanenko. During 1977–1978, Tivanenko led the archaeological expedition of the Ethnological Museum of Peoples of Transbaikalia which focused on searching for and recording of rock art sites of the Republic of Buryatia. As many other rock art researchers of East Siberia of that time, Tivanenko also conducted excavations at rock art sites in order to provide age and to study religious activities. These materials later became the basis for more detailed study on the so-called sanctuaries of East Siberia (Tivanenko 1989, 1990).

In 1987, the revision of rock art sites of the Upper Lena River was started by Larisa V. Mel'nikova, Vadim S. Nikolaev, and N.I. Dem'janovich. As a result of the 20-year research, the Shishkino rock art site, as well as other sites of the Upper Lena basin, was redocumented using more accurate techniques. Dem'janovich studied the geomorphology of the Shishkino rock cliff, and her conclusions about the rock destruction process allowed her to clarify the chronological sequence for the rock art (Fig. 2). Unfortunately, only the data on the Shishkino site have been published to this day (Mel'nikova et al. 2011, 2012).

In the late 1980s–1990s, new rock art sites were discovered on the western coast of Lake Baikal and in the Khilok River basin, Transbaikalia. New sites from other areas of Transbaikalia were also reported. During the last few decades, several archaeological inventories of Buryatia were prepared, which provide brief information about site location, condition, and time of examination, and they also include some

Rock Art of Siberia: Baikal and Transbaikal Regions, Fig. 2 Chronological model of the Upper Lena basin rock art after Mel'nikova et al. (2012). The table is arranged by I. Ponomareva. 1–11, Shishkino (after Mel'nikova et al. 2011); 12, Upper Lena; 13, Tal'ma (after Mel'nikova and Nikolaev 2006)

site reports which were not previously published (see Bazarov and Namsaraev 2011). These inventories did not include Zabaykalsky Krai, and the fullest information on rock art sites of the region can be found in the *Small Encyclopedia of Transbaikalia* (Geniatulin 2011).

R

Key Issues/Current Debates

The Earliest Rock Art

Until recently the oldest rock art of Siberia was believed to be the animalistic images discovered by Okladnikov at the Shishkino rock art site, which, as he assumed, belonged to the Paleolithic Age. These were two figures of wild horses and a large figure of an aurochs. His main argument was that these animals belong to the Pleistocene fauna, since their bones were unearthed from the Paleolithic sites of the region. In the Neolithic and Bronze Age, these animals could not have survived, because the climate and landscape changed, and this territory was covered by dense taiga. Other arguments referred to the stylistic appearance. Okladnikov emphasized that these figures differed from other groups related to either the Neolithic or Bronze Age or Iron Age (Okladnikov and Zaporozhskaya 1959). However, this dating was mainly criticized for its stylistic analogy of these archaic-looking images with Franco-Cantabrian cave art. The later research of the Shishkino rock art site proved that the rock surface itself on which the bull was depicted could not have appeared earlier than the Bronze Age. The surface with the horses could have been exposed as early as the Late Neolithic Age (Mel'nikova et al. 2012). Three more sites, Ushkaniy island and Dolgiy Rapids in the Angara River basin and Tal'ma in the Upper Lena River basin, yielded pictures which were related to the Paleolithic Age. These are three amorphous zoomorphic figures which were interpreted by Okladnikov as rhinoceroses. However, this interpretation raises doubts.

A number of sites in Eastern Transbaikalia and adjacent northwestern Amurskaya oblast have been related to the final Pleistocene–Early Holocene period (Figs. 3 and 4). These are Byrka, Nyukzha, Sredneshaikino, and Butikha (Mazin 1986). The Byrka site was discovered in 1983 and contained 20 panels with more than 80 painted designs, among which extinct fauna was present. It included a figure of a rhinoceros and numerous figures of steppe bison. According to dates available for the extinction of fauna, the earliest group of images at this site was then dated to 18,000–12,000 uncal BP. The Nyukzha site yielded even more solid evidence. The excavations undertaken at the site revealed that the cultural layer was covering a fallen panel with a painting of an animal. This layer yielded pieces of ochre, and some stone artifacts recovered from the layer had stains of red paint on them. One stone flake even featured an ochre fingertip. However, the site was dated only based on the typology of stone artifacts which were related to the Paleolithic Dyuktai culture of Northeast Asia dated to 35,000–10,500 BP. The sites Sredneshaikino and Butikha were related to the Early Holocene period based on stylistic similarity with the images at Byrka and Nyukzha, and the typological dating of artifacts recovered from the lower cultural layers excavated in the vicinities of the panels with the paintings. Another site, Shaman-Gora featuring stylistically similar figures of steppe bison, was discovered in the 1990s (Fig. 5). Although the authors insist upon its Late Neolithic–Bronze Age date, the arguments are not convincing since they refer to the finding of osseous remains of the steppe bison unearthed at the Ust'-Menza 1 site, which were not directly dated.

Thus, there is no rock art in the Baikal region which can be related to the Paleolithic Age. It appears that the earliest surviving rock art sites belong to the Neolithic. However, there are sites in Eastern Transbaikalia that can be quite old. The problem is that the arguments do not have a solid base. The interpretation of depicted animals as rhinoceroses and steppe bison may be doubtful. The relationship between the excavated cultural layers with rock art panels is not obvious, and the ochre uncovered from the layers was not analyzed to determine if it is the paint by which the figures on the panels were painted. Moreover, no radiocarbon dates were yielded for the excavated sites including the Nyukzha site. Therefore, these sites can be considered as possible candidates for being the earliest rock art sites in the region, along with several sites in the Altai Mountains (Molodin and Cheremisin 2007), but their age demands further investigation.

The Rock Art Traditions of the Baikal Region in the Neolithic, Bronze, and Early Iron Ages

Neolithic rock art was first identified by Okladnikov, who characterized it as having a focus on a single motif – the elk. Elk images dominate the rock art sites of the taiga zone, which are mostly found on the banks of the Lena and Angara Rivers and their tributaries. The first group of elk depictions has a naturalistic manner of representation, features which are distinctive for the animal such as the beard, nose, eyes, and ears are shown, and the dynamics of movement expressed (Fig. 6). The second group featured a more simplistic manner of depiction where no details were shown, and the head has a paraboloid shape. The former was dated to the Early Neolithic and the latter to the Late Neolithic based on analogies in portable art.

The early naturalistic elk images were interpreted in terms of the fertility cult. The elk played an important role in the economy of the taiga peoples, and it was one of the most common characters in the mythology of indigenous peoples of Siberia (Okladnikov 1966). Okladnikov illustrated the point by rites and rituals of the Evenks, which were aimed at elk reproduction (Okladnikov and Zaporozhskaya 1959). The second group was assumed to indicate the development of hunting magic, because there were examples of archers next to simplistically depicted elk figures, elk figures with arrows in their bodies and depictions of rows of vertical

Rock Art of Siberia: Baikal and Transbaikal Regions, Fig. 5 Shaman-Gora (Ulan-Khada) site. (Original and DStretched photograph by I. Ponomareva)

lines which were interpreted as game drive structures (Okladnikov 1966).

The rock art of the Bronze Age, according to Okladnikov (1966), considerably differed from that of the Neolithic. In general, the images became smaller, the painted pictures prevailed, and the stylistic manner appeared to be more abstract in contrast to naturalistic Neolithic images. In terms of the content, the set of motifs is dominated by anthropomorphic figures which include dancing figures, sometimes shown as in a half-sitting pose, and many of them are phallic. Also, images of boats appeared in this period, which were quite abstract and depicted with anthropomorphic figures shown as vertical lines (Okladnikov 1966).

In the Angara River basin, two complexes were identified. The first included the images of faces/masks. They were correlated with the face/mask depictions of the Okunev culture present in the Minusinsk basin in the Early Bronze Age. The second included anthropomorphic figures with horns, upraised arms, and rhomboid legs which were dated to the Late Bronze Age (Okladnikov 1966). The latter was initially described based on the materials of the Shishkino rock art site where anthropomorphic figures with horns and upraised arms were found in boats in a composition with a figure of a deer which had its head turned back and vertical lines along with a spiral on the rump. Okladnikov considered it to be similar to the deer figures found on the deer stones in

Rock Art of Siberia: Baikal and Transbaikal Regions, Fig. 6 Second Kamenny Island. (© St. Petersburg Branch of the Archive of the Russian Academy of Sciences (SPbB ARAS), Saint Petersburg branch, Fund # 1099, Inv. 1, File # 872)

Transbaikalia and metal artifacts of the Scythian type and therefore dated the complex to the Late Bronze Age–Early Iron Age (Okladnikov and Zaporozhskaya 1959).

Another area with striking Bronze Age rock art is the eastern coast of Lake Baikal where two sites, Sagan-Zaba and Aya bay, are present. The petroglyphs of Sagan-Zaba are located on a high white marble cliff which towers over the lake. A prevailing motif here is large anthropomorphic figure with broad shoulders, thin waists, and short legs. The figures give an impression that they are dancing, and some of them have horns and stripes on the torso. The site was dated to the Early Bronze Age based on the analogy with anthropomorphic figures depicted on the ceramic vessels of the Samus' culture present in West Siberia in the Early Bronze Age. Another argument was that, in the vicinity of the rock art site, the cultural remains of the Glazkovo culture of the Early Bronze Age were unearthed. The Aya bay site was related to the Late Bronze Age, since the anthropomorphic figures present there, although being similar to those at Sagan-Zaba, were smaller and more simplistic in their stylistic appearance and were shown in an X-ray manner.

The pictures of the Sagan-Zaba and the Aya bay rock art sites allowed Okladnikov to suggest cultural contacts across Eurasia, from Scandinavia to Lake Baikal, in the Bronze Age. These are "dancing" anthropomorphic figures, boats, and swans. The latter is a motif rarely found in Siberia but present in the rock art of Fennoscandia. This hypothesis was supported by the phenomenon of a wide distribution of the Glazkovo white nephrite rings and Seima-Turbino bronze artifacts. Considering the anthropomorphic imagery of the Baikal Bronze Age rock art, which featured many shamanistic traits such as headdresses, X-ray style, dancing manner, and depictions of rings which can be interpreted as drums, Okladnikov inferred the emergence of shamanism, which therefore was indigenous in Siberia (Okladnikov 1974).

The rock art of the Early Iron Age in the Baikal region is related to the deer stone style distributed throughout the Central Asia and South Siberia and associated with the early nomads (tenth to fifth centuries BC) (Savinov 1990, see also Jacobson-

Tepfer 2015). Depictions of deer resembling figures found on deer stones were identified by Okladnikov at the Sakhyurte rock art site on the western coast of Lake Baikal (Okladnikov 1974). In the Angara River basin, the Manzya site was related to this period based on three depictions of cauldron of Scythian type (Okladnikov 1966). Later a number of petroglyphs in deer stone style were discovered at the Shishkino site in the Upper Lena River basin (Fig. 2, *7–9*), the area where also bronze casting objects of Scythian animal style were found in the context of Korsakov's treasure. The petroglyphs were dated from seventh to second centuries BC (Mel'nikova et al. 2012). However, the rock art of the Late Bronze Age–Early Iron Age is more diverse and abundant in the adjacent, Transbaikal region.

The Rock Art Traditions of the Transbaikal Region in the Neolithic, Bronze, and Early Iron Ages

According to Okladnikov's model, only few images, elk figures at the Bain-Khara Angirskaya site, could have been dated to the Neolithic Age because of their naturalistic manner of depiction. They were defined as forest, or hunting, rock art group which was generally dated to the Bronze Age (Okladnikov and Zaporozhskaya 1970). Later Alexander Mazin, whose fieldwork mainly occurred in Eastern Transbaikalia, Upper Amur River basin, and Yakutia, the regions mostly covered by dense taiga forest, identified several rock art style appearances of which was related to the Neolithic Age (Fig. 3) (Mazin 1986).

The taiga rock art style included a naturalistic image of a deer and zoomorphic figures with paraboloid heads present at the Srednyaya Nyukzha and Byrka sites (Fig. 3, *3, 4*). Their age was established by excavations which yielded Early Neolithic artifacts. According to Mazin (1986), in the Late Neolithic Age, the taiga style split into two coexistent styles named hunting and reindeer herding. The former is localized in Transbaikalia and includes depictions of elk from the Ust'-Tsoron site dated to the Late Neolithic and anthropomorphic figures with horns which are related to the Early Bronze Age based on analogies on ceramic vessels of the Glazkovo culture. The latter, reindeer herding, is present in Amurskaya oblast and Yakutia and is characterized by anthropomorphic figures in association with reindeer where they appear to ride or lead them. This style also continues into the Bronze and Iron Ages.

Mazin identified another style, the steppe style, in the steppe zone and dated its emergence to the sixth–fifth millennia uncal BC based on excavations at the Urulyungui site (Fig. 3, *7*). However, this is the only evidence for such early age. The style is represented by the same set of motifs and their fashion as Okladnikov's Selenga group (see below) and is related to the Bronze Age.

The rock art of the Iron Age in the forest zone of Eastern Transbaikalia and the Amur region, according to Mazin (1986), is represented by two styles, the reindeer herding, which emerged in the Late Neolithic, and mythical, the chronological boundaries of which could not have been well defined. The latter was characterized as featuring mythical scenes with serpentlike creatures.

Although Mazin identified several Neolithic traditions, most of the Transbaikal rock art is related to the Bronze and Early Iron Ages, and the dominating type of rock art was identified as Selenga group (Fig. 7) after the core area, the Selenga River basin, where the sites are concentrated (Okladnikov and Zaporozhskaya 1970). To date, the sites exhibiting the motifs and elements characteristic for the Selenga group are found in the area which extends from the northwestern coast of Lake Baikal in the north to Ulan-Bator in the south and from the Dzida River basin in the west to the Onon and Vitim River basins in the east (Tivanenko 1990). The sites of the Selenga group are usually found in the steppes and forest steppes, on isolated rock outcrops, and sometimes in shelters and caves.

The Selenga sites often dominate a picturesque landscape. All Selenga rock art was made by red paint and included the following motifs: (1) so-called yards-enclosures of different shapes such as rectangular, square, oval, and circular, with other motifs depicted inside them such as rows or chaotic assemblages of dots and anthropomorphic and ornitomorphic figure,

Rock Art of Siberia: Baikal and Transbaikal Regions, Fig. 7 Mondogor-Khabsagai site. Selenga group. (Original and DStretched photograph by I. Ponomareva)

(2) ornitomorphic figures with spread wings shown as if flying and seen from underneath, and (3) anthropomorphic simplistic figures, often shown in rows. This group was related to the slab grave culture of the Late Bronze Age–Early Iron Age based on few analogous images found on bronze knives typologically dated to this period.

In addition to the age determination, Okladnikov developed the interpretation heavily relying on the ethnography of the Central Asian and Caucasian peoples which allowed him to infer that the rock art sites of the Selenga group could have played an important role in the spring rites related to the fertility cult. When considering another common motif, the images of birds of prey, it was noted that eagles were assistants and companions of Siberian shamans. In the Siberian ethnography, the eagle also has a feature of culture hero and related to myths about ancestors and tribe patrons.

The rock art sites of the hunting group mentioned above did not yield the motifs characteristic for the Selenga group. Although the area of this tradition partly overlapped that of the Selenga group, the sites were found in forested areas of Transbaikalia. The motifs included anthropomorphic figures, many of which had hornlike headdresses and were part of scenes with the depictions of wild fauna such as deer, elk, bear, and boar. Okladnikov considered these images as being more dynamic and expressive in their style and considered them as being synchronous with the dominating Selenga group since some

Rock Art of Siberia: Baikal and Transbaikal Regions, Fig. 8 Baga-Zarya site. Kyakhta group. (Photograph by I. Ponomareva)

zoomorphic figures exhibited slight stylistic resemblance with deer stone style. Okladnikov considered the sites of the hunting group as having a different function and related to the hunting magic.

Another group that was identified by Okladnikov is Kyakhta group (Fig. 8). In contrast to the groups described above found on a huge territory, the Kyakhta group is present only in the southern part of Buryatia and considerably differs in its geo-ecological setting, technique, and imagery. The sites are represented by the concentrations of basalt boulders scattered on hills. Petroglyphs, namely, pecked, engraved, and scratched figures present on these boulders, are dominated by the depictions of ibex, deer, and wolves. Okladnikov related this group to the Late Bronze Age–Early Iron Age since the figures have the attributes of the deer stone style.

The diversity of the Bronze–Iron Ages rock art traditions and styles of Transbaikalia will be complete after another type of rock art, the deer stones, is considered. The deer stones are decorated stone stelae which are found throughout the steppes of Eurasia and related to various sepulchral and ritual complexes of the early nomads (1000–500 BC) (Savinov 1994). They were named deer stones by the earliest explorers of Central Asia because many of them are decorated with stylistically distinct figures of deer. However, the deer stones are very diverse in their form, subject matter depicted, and the compositions of images. More than 500 out of 700 known deer stones were found in Mongolia, where they are related to the khirigsuurs, large and complex ritual sites. In Transbaikalia only a dozen is known, and the region is considered as a periphery of the deer stone area. Here they were found reused in the grave construction of the slab grave culture.

The Rock Art of the First to Second Millennia AD

In the Baikal region, the rock art of this period is present at the sites of the Upper Lena River, on the western coast of Lake Baikal (the Sagan-Zaba and Aya bays, the Yelgazur I and Orso sites, and the Nutgei area), and in the basins of the Unga and Kuda Rivers, tributaries of the Angara River (Mel'nikova et al. 2012; Okladnikov and Zaporozhskaya 1959; Nikolaev and Mel'nikova 2008). The rock art was made by various techniques of engraving, incising, rubbing, and scratching.

According to Mel'nikova et al. (2012), there are three chronological groups. The first group was related to the early medieval Kurumchi archaeological culture and dated to second–eleventh centuries AD. The culture is identified with the Kurykan tribe which is considered among the ancestors of the Yakuts and Buryats. The rock art is very realistic in the sense that it depicts diverse scenes from everyday life, such as hunting, battles, nomadic migrations,

and movements of riders with standards, naturalistically and in detail. The animalistic imagery in addition to elk, deer, and horse also included camels. Several scenes were accompanied by Turkic runic inscriptions. The second group was dated to twelfth–fourteenth centuries AD and included images which can be described as more static and simplistic compared to the first group. The third group was related to sixteenth–nineteenth centuries AD and belongs to the indigenous Buryat peoples and Russian Cossacks. This rock art was incised or scratched and depicted detailed figures of riders-archers, Orthodox crosses and domes, and small ships which were accompanied by inscriptions and dates.

In Western Transbaikalia, the medieval rock art is concentrated in South Buryatia, where it is present at the sites of the Kyakhta group and the Sarbadui site. Some images were painted, although the majority of figures were incised and they depict scenes of nomadic life similar to those abundantly present in the steppes of the Angara and Upper Lena basins (Okladnikov and Zaporozhskaya 1969, 1970). Several images dated to the Middle Ages were found in other areas of Western Transbaikalia, such as the Uda and Khilok River basins (Tivanenko 1990). In Eastern Transbaikalia, no rock art belonging to the Middle Ages has been identified yet. Mazin dated several sites to the second millennium AD, but they are located in the adjacent Amur region (Fig. 3, *10, 11*).

International Perspectives

This entry considers only rock art present in the territory of the Russian Federation, but some of the traditions and styles discussed above are present more widely and found not only in Asia but also in European parts of the continent. In terms of international interest, research in many parts of Asia has been carried out by international teams of scholars, and one of the outcomes is that the research on archaeology and rock art of the region is present in many languages and universities all over the world.

Future Directions

Numerous topics need academic attention. First, the most important issue is the conservation and preservation of Siberian rock art. Many outstanding rock art sites have been badly damaged by vandalism, e.g., Byrka and Sokhatinny Kamen' in Transbaikalia and Shishkino and Vorob'yovo in the Baikal region. Even though there are examples of sites well preserved and managed due to endeavors of passionate researchers and amateurs (e.g., Oglahkty in Khakasia), no policy exists in Russia specifically devoted to look after rock art. Second, in terms of chronology, the existing models need reconsideration since most of them were created a half a century ago. No chronometric techniques have been applied, and scientific approaches would be also of high interest. Third, some of the interpretations offered in the recent decades are disputable, possibly because the rock art of the Baikal and Transbaikal regions has seen insufficient scholarly interest, and its rise could result in better understanding of all aspects of this rock art which is an open field for various methodological approaches applied elsewhere.

Rock Art of Siberia: Sakha/Yakutia Republic

Irina Ponomareva
School of Humanities, Languages and Social Science, Griffith University, Gold Coast, QLD, Australia

Introduction

Siberia is an extensive geographical region, and it has a rich body of rock art. This chapter is focused on one of the largest regions of Siberia and the Russian Federation, the Sakha/Yakutia Republic. It commences with an outline of the timeline and geography, continues with the history of rock art scholarship, and then is followed by a review of key issues and current debates. The rock art of Yakutia has not seen vigorous debates, but several topics have been in focus by rock art researchers, such as chronology, ancient ontologies, and the origins of shamanism. The strong tradition in Siberian scholarship to approach rock art sites as open-air sanctuaries is also reviewed. The chapter ends with a discussion of the international perspectives and future directions for the rock art of Yakutia.

Definition

Sakha/Yakutia Republic is a vast Russian region which occupies more than three million km^2 in North-Eastern Siberia. Its northern zone lies above the Arctic circle, the Tundra belt stretches below, and the southern section of Yakutia is covered by dense Taiga forest. One of the largest Siberian rivers, the Lena river, flowing into the Arctic Ocean, constitutes the major river drainage. To date, more than 100 rock art sites are known in Yakutia, and the majority are found in Southern and Central Yakutia, in the basins of the Lena river and its tributaries, the Aldan and Olyokma rivers. However, several sites are present in the North, in the basins of the Indigirka and Olenyok rivers (see Fig. 1).

It was suggested that Yakutia was occupied by early human populations in the Middle Paleolithic, although the exact dates of this event have been vigorously debated. The oldest known rock art was related to the Late Paleolithic Dyuktai culture dated to 35000–10500 BP, and the rest of the rock art was related to the following archaeological cultures (Mochanov and Fedoseeva 2013; Alekseyev and Dyakonov 2009):

Rock Art of Siberia: Sakha/Yakutia Republic, Fig. 1 Yakutia/Sakha Republic: Rock art sites and rivers mentioned in the text. 1 – Kirbei, 2 – Tangaralakh, 3 – Dzhampa, 4 – Suruktakh-Khaya-at-Markha, 5 – Churu, 6 – Sinsk, 7 – Petrovskoye, 8 – Toyon-Ary, 9 – Tokko, 10 – Basynai, 11 – Krestyakh, 12 – Tungurchakan, 13 – Nyukzha, 14 – Srednyaya Nyukzha, 15 – Kuskangra, 16 – Bes-Yurekh, 17 – Ilim-Orgo-Yurekh, 18 – Onneyu, 19 – Maya, 20 – Sygdar'ya, 21 – Tomtor, 22 – Malotarynskaya, 23 – Suturuokha, 24 – Shishkino

The Mesolithic Sumnagin culture – 10,500–6000 BP
The Early Neolithic Syalakh culture – 6900–5500 BP
The Middle Neolithic Bel'kachi culture – 6200–4200 BP
The Late Neolithic – Early Bronze Age Ymyjakhtakh culture – 5000–3000 BP
The Bronze Age Ust'-Mil' culture – 3400–2000 BP
Early Iron Age- 2700–1500 BP
Middle Ages – 1500–400 Centuries AD

Historical Background

The first information about rock art in Yakutia appeared in the late nineteenth century. These were the sites near the town of Olyokminsk (1888) and at the Maya River (1893); the latter was examined again by Yakov V. Stefanovich the following year. In 1897 Nikolai A. Vitashevsky (Mikołaj A. Witaszewski – Polish exile) published the first detailed report on Yakutian rock art. He visited, meticulously described, and accurately redrew pictures at two sites at the Olyokma River: Krestyakh and Basynai. The local Tungus people, who provided the information about the sites to Vitashevsky, also advised him about two more sites – at the Nyukzga River and at the Tungurchakan River, but Vitashevsky could not locate them. In 1898, another student of Yakutia, Ivan I. Mainov, reported seeing a rock art site at the Amga River (Onneyu) while studying the Tungus people. He also conveyed information about rock art at the Sinyaya River, a tributary of the Lena River, and mentioned being shown signs on a rock at the Bordakh River in the Indigirka River Basin (Kochmar 1994).

More Yakutian rock art sites were reported in the beginning of the twentieth century: in 1900 near the Elanskaya station at the Lena river by P.S. Alekseev; in 1912–1913 at the Nyuya River; in 1915 at the Olyokma river, near the mouth of the Oyulakh spring, by A.A. Gaiduk; and in 1915 at the Lena River by M.P. Ovchinnikov (Okladnikov and Zaporozhskaya 1972; Kochmar 1994). Although the rock art of Yakutia became known much later than the rock art of other Siberian regions, the data on Yakutian sites grew rapidly almost every year.

In 1923, the investigations of the rock art of the Lena, Olyokma and Maya rivers were led by Yefim D. Strelov, the first professional Yakutian archaeologist. In 1924, the importance of studying pictures and inscriptions on rocks was pointed out by Yakutian historian Grigory A. Popov (see Kochmar 1994). In 1921–1923, ethnographer Gavriil V. Ksenofontov undertook the archaeological exploration of the Middle basin of the Lena river to study the origins of the Yakuts. Ksenofontov recorded nine rock art sites on the left bank of the Middle Lena River and provided ten tables with drawings. In analyzing this rock art, he relied upon the ethnographic data of the Yakuts, Buryats, Tungus, and Uygurs (Ksenofontov 1927). In general, his work differed considerably from previous brief reports in that it was an academic paper with a grounded argument. In 1935, his materials were utilized in the studies of the development of the Yakutian language by philologist Platon A. Oyunsky. In 1926–1928, ethnographer Viktor N. Vasil'ev surveyed the Tungus of the Aldan-Maya basin and the Ayan-Okhotsk area and enriched the knowledge of previously reported sites. In 1931, geologist N.B. Kyakshto reported on a rock art site, the Shaman-stone (now known as the Srednyaya Nyukzha), located at the Nyukzha river and provided a drawing of the rock art. Some reports of rock art also appeared in a local newspaper, the "Avtonomnaya Yakutia." These included rock art sites: at the Markhachan, Olyokma and Tokko rivers in 1924; and the Amga and Markha rivers in 1929. Rock art sites of the Olyokma, Nyukzha and Maya rivers were also mentioned in E.R. Pekarsky's Dictionary of the Yakutian language (see Kochmar 1994; Okladnikov and Mazin 1976).

The next stage in the studies of Yakutian history started with the foundation of the Institute of Language and Culture of the Yakut Autonomous Soviet Republic in 1935. In 1939, the Institute sent local ethnographer A.A. Savin to explore

the basin of the Middle Lena River, from which in the early 1920s Ksenofontov reported nine rock art sites. Savin reported ten sites, but only three of them were those recorded by Ksenofontov (Okladnikov and Zaporozhskaya 1972).

In 1940, Alexey P. Okladnikov commenced the Lena historic-archaeological expedition, and for several years he explored the basin of the Lena River from the source to the mouth. The result was his seminal work on the prehistory of Yakutia in which the rock art of the Upper and Middle Lena River Basins was considered along with other archaeological data (Okladnikov 1955), although the entire body of work on rock art was completely published 20 years later (Okladnikov and Zaporozhskaya 1972; Okladnikov 1977).

Since the late 1950s, studies of Yakutian rock art have been continued by a new generation of archaeologists. In the 1950s–1960s, new rock art sites were discovered at the Amga, Maya, and Olyokma rivers. In 1958 and 1965, the outstanding sites of Krestyakh and Basynai at the Olyokma River were re-examined, and in 1955, the Tomtor rock art site, on the Indigirka river, was reported by G.A. Pytlyakov (see Kochmar 1994). The works of this period differed from brief reports published previously. All of them attempted to provide rock art with age, for instance, Svetlana A. Fedoseeva compared the sites discovered at the Amga river with those found elsewhere and suggested their Neolithic age. Geologist V. Frolov related the site which he discovered in the Upper section of the Olyokma river to the end of the Paleolithic Age because one of the depicted figures was an aurochs (see Kochmar 1994). Yakutian rock art was also a source for the studies of ancient Turkic inscriptions (Bernshtam 1951) and the art traditions of indigenous people of Siberia. In 1969–1978, Yakutian archaeologist Nikita D. Arkhipov re-examined many outstanding sites such as Krestyakh and Basynai, where he revealed new panels, and discovered two sites at the Olenyok river (see Kochmar 1994). Arkhipov purposefully searched and studied accumulations of artifacts, considered as offerings, at rock art sites which therefore were seen as sacred places. This became an important part of the subsequent studies of the Yakutian rock art.

In 1965–1976, Alexander I. Mazin carried out extensive surveys of rock art sites in the basins of the Olyokma, Aldan, and Amga river which resulted in two monographs (Okladnikov and Mazin 1976, 1979). His focus on studying and excavating the cultural deposits near the rock art panels allowed him to further elaborate on the chronological model developed earlier by Okladnikov (see the next section).

In 1977, a long-term period of rock art research commenced which is associated with the name of a prominent archaeologist Nikolai N. Kochmar. During the years 1970s–2000s, his expedition explored the basins of the Olyokma, Lena, Amga, Indigirka, Aldan, Chara, Buotuma, Tyaka, and Tokko rivers. The result was 115 recorded rock art sites and more than 5000 recorded rock art pictures. The collected data were analyzed and synthesized in Kochmar's monograph on the rock art of Yakutia, which is the most complete summary of all the information on Yakutian rock art to date (Kochmar 1994). However, the quality of the graphics was not an improvement on the Okladnikov's books published in previous decades; Kochmar's book included black-and-white drawings of rock art images and drawings of locations and general views at rock cliffs. Kochmar, similar to his predecessors, also focused on studying cultural deposits in the vicinity of the rock art sites and related them directly to the images.

Between 2000 and 2003, some rock art sites along the Lena and the Olenyok rivers were investigated by Polish-Yakut archaeological-ethnological team, particularly from the perspective of their relations to shamanism. This research resulted with fresh English publications (Rozwadowski and Knurenko 2002; Rozwadowski 2014, 2017a, b).

After Kochmar's decease in 2008, no big projects have been undertaken, although several rock art sites have been re-examined and a few have been discovered (e.g., Suruktakh-Khaya-at-Markha and Dzhampa).

Key Issues/Current Debates

Cultural History

Ksenofontov was the first to infer the age of the Yakutian rock art and their ethnic attribution. In surveying the rock art sites in the Middle Lena basin, he observed their stylistic unity and inferred that they belonged to a single ethnic group. Ksenofontov did not believe that the painted designs could have survived more than 1000 years. Moreover, the imagery included depictions of horses and cows. All this implied that the rock art could be attributed to the Yakuts. He pointed to the resemblance of the Lena anthropomorphic figures with those reported at the Maya and Olyokma rivers and Lake Baikal and suggested that they were made by a single ethnic group or closely related groups (Ksenofontov 1927).

The first detailed and grounded chronological model was established by Alexey Okladnikov. Based on the evidence from the cultural deposits unearthed at the Suruktakh-Khaya-at-Markha (Fig. 4) and Churu sites, he identified the Neolithic rock art which was named "monumental-realistic" style and included naturalistic depictions of elk. The next identified group was related to the Bronze Age, the period of Glazkovo culture of the Baikal region and Ymyjakhtakh culture of Yakutia, and included anthropomorphic figures and more simplistic depictions of elk. Another group of images was defined as "pictures-ideograms" and provisionally dated to the 1st millennium AD. It was suggested that these images may indicate the emergence of a writing system. The youngest group of rock art pictures included so-called ancient Yakutian and ancient Tungussic rock art. This included several shamanistic scenes and graffiti.

Okladnikov's model considered rock art only in the Lena basin. Mazin's seminal research allowed further development of the model which also included the rock art of the Olyokma and Aldan river basins (Okladnikov and Mazin 1976, 1979). Rock art groups identified by style and superimposition analysis were then correlated with archaeological cultures based on the analysis of unearthed cultural deposits at the rock art sites. Kochmar elaborated the model by including more data and evidence, although the methodology remained the same.

The earliest surviving rock art was hypothesized to be of the Upper Palaeolithic age (Fig. 2, 19–23). This contains figures of aurochs, horses, elk, and deer which are characterized by a naturalistic manner of depiction, present at the Tokko site in the Olyokma basin. Okladnikov and Mazin (1976) suggested they were painted at least 4000 BP. The main argument for this was that aurochs and wild horses are characteristic for the Pleistocene period. Moreover, these figures, the paint of which is very faint, occupy central positions on the panels and were superimposed by later images. Kochmar re-examined the Tokko site and concluded that the figure of aurochs was actually a depiction of Steppe bison, thus supporting the Palaeolithic attribution of this rock art (Fig. 3). However, the Palaeolithic attribution of some Yakutian rock art requires reassessment. The researchers pointed to the stylistic resemblance of the Tokko figures with those present at the Shishkino rock art site in the Upper Lena basin which Okladnikov related to the Palaeolithic age based on the same grounds (Okladnikov and Zaporozhskaya 1959). The later research of the Shishkino rock art site showed that the rock surface itself on which the aurochs was depicted could not have appeared earlier than the Bronze Age. The surface with the horses could have been exposed as early as the Late Neolithic Age (Mel'nikova et al. 2012).

The Early Neolithic rock art was identified based on the excavations of the Nyukza rock art site, located in the adjacent Amurskaya oblast, where cultural deposits were found over a panel featuring a zoomorphic figure with a paraboloid head (Fig. 2, 14). Stylistically similar figures are present at the Srednyaya Nyukzha and Tokko sites in the Olyokma basin (Fig. 2, 15, 16). The artifacts unearthed from the Nyukzha site were dated based on typological similarities with artifacts of the Syalakh archaeological culture (Okladnikov and Mazin 1976). However, later, this attribution was reconsidered, and the artifacts were claimed to belong to the Late Palaeolithic age; however, no

Rock Art of Siberia: Sakha/Yakutia Republic, Fig. 2 Chronological model of the rock art of the Aldan and Olyokma river basins after Okladnikov and Mazin (1976, 1979). The table arranged by I. Ponomareva. Olyokma basin: 2 – Tungurchakan, 6, 8 – Basynai, 7, 15, 16, 19-23 – Tokko, 10, 11 – Krestyakh, 14 – Nyukzha (after Okladnikov and Mazin 1976); Aldan basin: 1 – Ilim-Orgo-Yurekh, 4, 12 – Bes-Yurekh, 3, 5, 9, 13, 17 – Maya, 18 – Sygdar'ya (after Okladnikov and Mazin 1979)

Divisions into periods (according to U.A.Mochanov)	Archaeological cultures of Yakutia	Petroglyphs	Typical artifacts of ancient cultures of Yakutia
Paleolithic 36 - 10 thousands of years ago	D'uktai Culture		
Holocene Paleolithic 10,5 - 6,2 thousands of years ago	Sumnagin Culture		
Early Neolithic 6,2 - 5,2 thousands of years ago	Syalakh Culture		
Middle Neolithic 5,2 - 4,1 thousands of years ago	Bel'kachi Culture		
Late Neolithic 4,1 - 3,3 thousands of years ago	Ymyjakhtakh Culture		
Bronze Age 3,3 - 2,4 thousands of years ago	Ust'-Mil' Culture		
Early Iron Age 2,4 - 0,5 thousands of years ago	Cultures of the Early Iron Age		

Rock Art of Siberia: Sakha/Yakutia Republic, Fig. 3 Chronological model of the rock art of Yakutia/Sakha Republic after Kochmar (1994)

R

radiocarbon dates have been obtained (Mazin 1986). In the Aldan basin, figures of elk at the sites of Maya and Sygdar'ya were dated to the Early Neolithic based on their larger size compared to other images and their central positions on the panels (Fig. 2, 17, 18) (Okladnikov and Mazin 1979).

There is some debate where the following group belongs to the Early or Middle Neolithic. It included figures of elk in a naturalistic manner of depiction. In some cases, these figures were accompanied by linear marks and rows of vertical lines which were interpreted as game driving structures. This group of images has analogies throughout the forest zone of Siberia at the rock art sites of the Upper Lena, Angara, and Tom rivers. These naturalistic elk figures were identified as Angara style and have been a focus of debates concerning their age and cultural attributions (see Kovtun 2001). Okladnikov and Mazin (1976) related this group to the Middle Neolithic Bel'kachi culture based on the excavations at the Krestyakh rock art site (Fig. 2, 10–13). Later Kochmar claimed the Early Neolithic age of this group of naturalistic elk figures by drawing on the same stylistic similarity with naturalistic elk depictions in the Baikal region where Okladnikov related them to the Early Neolithic (Fig. 3) (Okladnikov 1966). Another argument was concerning the Syalakh attribution of the stone artifacts unearthed at the Kuskangra rock art site (Kochmar 1994), although the stylistic unity of the Kunkangra elk depictions with this group is questionable.

While Okladnikov and Mazin (1976, 1979) related the group of naturalistically depicted elks to the Middle Neolithic Bel'kachi culture, Kochmar (1994) attributed quite different groups of images to this period (Fig. 3). These are the zoomorphic figures with paraboloid heads that are stylistically similar to those dated to the Early Neolithic based on the Nyukzha site evidence. This group also included other zoomorphic figures with wedge-like and rectangular heads. Kochmar also related anthropomorphic figures of the Suon-Tiit site to this period based on the inferred association with cultural deposits excavated there. He pointed out that the rock art of the Middle Neolithic differed from the previous periods in that new motifs appeared, such as depictions of serpents and specific anthropomorphic figures with three-fingered hands, round heads and in some cases with phalli. According to Kochmar (1994), this imagery is an expression of shamanistic beliefs which can be seen in the rock art of later periods elsewhere in Siberia.

The next period in the Yakutian history was occupied by the Ymyjakhtach archaeological culture, which is considered as Late Neolithic, but at the same time it is synchronous to the Early Bronze Age Glazkovo culture in the Baikal region, where distinct rock art imagery was related to the Glazkovo period based on anthropomorphic depictions present on several pottery vessels (Okladnikov 1974). Later such pottery was also found in Yakutia dating to the same period. There is other evidence that suggests intensification of cultural contacts across Siberia in the 3rd–2nd millennia BC. This phenomenon can be clearly seen in the rock art of Yakutia attributed to this period which finds its counterparts as far as the Yenisey river basin. These are anthropomorphic figures with triangular bodies and horns/horn headdresses which are shown in various poses, such as adoration and dancing, and compositions, e.g., hunting and reindeer-herding scenes (Fig. 2, 5–9). Many of the figures are ithyphallic. The imagery, as in other parts of Siberia, also included depictions of boats with simplified anthropomorphic figures shown as vertical lines. This rich rock art group also included so-called "solar symbols" depicted as four-spike wheels and face-masks, a motif rarely found in East Siberia (Okladnikov and Mazin 1976, 1979; Kochmar 1994). Another group, which was related to the Ymyjakhtakh culture, is not so widely present in Siberia and found only in Yakutia and adjacent Amurskaya oblast. It includes animal depictions the legs of which are depicted as boots (Fig. 2, 7) (Mazin 1986).

The following period is the time of the Bronze Age Ust'-Mil archaeological culture dated to 3300–2000 BP. In the Aldan basin, a group of rock art was related to the late 1st millennium BC–early 1st millennium AD which included more diverse themes and scenes such as hunting

with dogs (Fig. 2, 3), boats and nets, reindeer-herding and reindeer-riding (Okladnikov and Mazin 1979). In the Olyokma basin, two sites, Tungurcha and Tungurchakan, were related to the 1st Millennium BC. They featured scenes of anthropomorphic figures with serpentine creatures and reindeer-herding scenes (Fig. 2, 2) (Okladnikov and Mazin 1976). Some of the images of the Bes-Yurekh site were related to the Iron Age because one figure of deer (Fig. 2, 4) had a slight stylistic resemblance with deer-stone style distributed throughout the Central Asia and South Siberia and associated with the early nomads (tenth–fifth centuries BC). Kochmar related "solar symbols," x-ray anthropomorphic figures, some shaman's depictions, boats and overturned anthropomorphic figures to this period (Fig. 3) (Kochmar 1994).

More recent rock art includes the site Ilim-Orgo-Yurekh in the Aldan basin which was broadly attributed to the 1st–2nd Millennia AD and included mostly abstract designs, such as rings, triangles, rectangular figures, crosses, and various lines (Fig. 2, 1) (Okladnikov and Mazin 1979). Kochmar also pointed out that the rock art of the 1st and 2nd Millenia AD is not large in number. Although the imagery is represented by the scenes that are also characteristic for the rock art of the earlier periods, such as reindeer-herding, hunting scenes and shamanistic rituals, their style appears to be more simplistic and artless (Kochmar 1994).

Ontologies

The first explorers who provided the information about rock art were also curious about its meaning. For instance, Nikolai A. Vitashevsky, who published the first detailed report on Yakutian rock art in 1897, informed on the Tungus' beliefs that the pictures were made by the mountain spirit *Khaya Ichchite*. The Tungus also believed that the spirit was responsible for the appearance and disappearance of images from the rock panels. Similar beliefs existed in the Aldan-Maya river basins. The Tungus in this area, according to ethnographer Viktor N. Vasil'ev, also noticed that the rock art pictures sometimes had become faint and sometimes bright which was explained by the activity of the "*master of the mount*" (see Kochmar 1994; Rozwadowski 2017b, 15–20).

The first researcher who attempted to methodologically approach the interpretation of the Yakutian rock art by drawing in ethnography was Gavriil Ksenofontov. He emphasized the multicomponential nature of the rock art meaning. Some scenes were suggested having ideographic memorial function, while others featured obvious shamanistic connotations. The famous Toyon-Ary scene (Fig. 5) was interpreted as a symbolic representation of the confrontation between the Yakut and Tungus. The figure of the cow symbolizes the stock-breeding Yakuts and the figure next to it is "piebald deer," the symbol of hunting, and reindeer-herding Tungus (Ksenofontov 1927).

Alexey Okladnikov also heavily relied on the ethnographic data. Drawing on the chronological model created for the rock art of the Lena river, he could show how the ideology expressed in rock art developed from hunting magic in the Neolithic through the emergence of the shamanistic beliefs

Rock Art of Siberia: Sakha/Yakutia Republic, Fig. 5 The famous scene of the Toyon-Ary rock art site in the Lena river basin. Original and DStretched. (Photo I. Ponomareva)

in the Bronze Age and eventually into the beginning of an ideogrammatic writing system. Siberian ethnography allowed the identification of several themes in the rock art of Yakutia. One of them was the Cosmic Hunt. A number of hunting scenes were related to this story present in the mythologies of many North Eurasian peoples, in which the Cosmic Elk stole a sun or a day and is pursued by a legendary hunter.

Shamanism

Shamanism is "supra-ethnic ritual and religious tradition" among the Siberian people (Rozwadowski 2014, 99), and it provides an interpretative context for some of the rock art of Yakutia (see Gogolev 2002; Rozwadowski 2014, 2017b). Okladnikov was the first to interpret several scenes in the rock art of the Middle Lena river as shamanistic (Okladnikov and Zaporozhskaya 1972). They included anthropomorphic figures with horn headdresses and dancing figures. The most famous and often-referred to rock art scene comes from the site at the Sinsk village (Fig. 7). In the center, there is an oval design with a cross inside, interpreted as a drum, and an anthropomorphic figure with horn headdress and vertical lines coming from the shoulders interpreted as shaman's attire.

It is obscure when shamanism emerged in Siberia. In Yakutia the only evidence is present in the rock art and its chronology is yet to be clarified. It is assumed that some form of shamanism could have appeared as early as the Neolithic Age (see Gogolev 2002). This view is based on Okladnikov's claim that the belief system has appeared as early as in the Late Neolithic-early Bronze Age, although Kochmar dated the appearance of this imagery to the Middle Neolithic (Kochmar 1994; Rozwadowski 2017b).

Open-Air Sanctuaries

An important theme related to the rock art sites was the Evenks' cult of Bugady which is the highest deity and lives inside the rocks which have prominent features, and rock art sites are among them. One of the symbols of Bugady was elk or deer, and Evenks by performing rituals and leaving offerings at the places where the deity resided aimed at the reproduction of game (Okladnikov and Mazin 1979). Therefore, rock art sites were a priori considered by researchers as open-air sanctuaries. The study of cultural deposits at the rock art sites was a strong focus established by Okladnikov. The study of the cultural deposits at the Suruktakh-Khaya-at-Markha (Fig. 4) not only gave clues on the age of the rock

art, but also provided evidence of the continuity of worshipping at this place. The offerings included various items of weaponry spanning from ancient stone arrowheads to modern bullets (Okladnikov and Zaporozhskaya 1972). Mazin reports finding accumulations of offerings at 37 sites out of 52 that he studied, while Kochmar drew on the data recovered from 56 such accumulations found at 19 rock art sites (Kochmar 1994; Mazin 1994).

The alternative interpretation of these accumulations as short-term camp sites was denied because these deposits were found at places which are not suitable for living, these were slopes, covered by rock sediments and in many instances located far from water sources. Mazin pointed out that modern people avoid visiting these sites so as not to disturb the spirits, and other types of archaeological sites, such as burial and settlements, are rarely found in the vicinities of rock art sites (Mazin 1994). However, the later phenomenon is rather the consequence of the difficulties in detecting archaeological sites in the forested landscape and therefore insufficient state of knowledge.

Mazin distinguished two types of offering places at rock art sites, namely, ground and enclosed. Ground offering places were just accumulations of offering left next to the rock art panels. This is the most commonly found type present from the end of the Pleistocene period to present day. Enclosed offering places feature stone constructions within which offerings were placed. These are found in the Steppe and Forest-Steppe zones of the adjacent Eastern Transbaikalia. Mazin concluded that rock art sites with offering places have been ancient sanctuaries.

Kochmar paid a lot of attention to documenting present-day sanctuaries found at rock art sites. He reported recording 24 such ethnographic sanctuaries at 17 rock art sites. These were idols-*shenkens,* anthropomorphous wooden sticks, which were placed toward rock art panels to mediate with Eneke-Bugady, the patroness of family and nature (Kochmar 1994; see also Rozwadowski 2014).

The Yakutian Runic Script

In 1895, in a speech at the session of Troitskosavsko-Kyakhtinsky division of Priamursky department of Imperial Russian Geographical Society, Dmitry Klements, ethnographer and archaeologist, informed about the presence of runic inscriptions in Yakutia, although he did not provide any details (Kochmar 1994). A half a century later, Okladnikov identified a group of rock art images as "pictures-ideograms" and inferred that they are evidence of a writing system (see Okladnikov and Zaporozhskaya

Rock Art of Siberia: Sakha/Yakutia Republic, Fig. 6 Yakutian runic inscription. The Petrovskoye site in the Lena river basin. (Photo I. Ponomareva)

Rock Art of Siberia: Sakha/Yakutia Republic, Fig. 7 Shamanistic scene at the Sinsk Village site. After Okladnikov and Zaporozhskaya (1972); see also Rozwadowski and Knurenko (2002) for more recent tracing

1972). Ivan I. Barashkov distinguished two groups: unidentifiable ideogramic signs and runic-like signs resembling Old Turkic script (Fig. 6). Some of the runic inscriptions of the second type were deciphered (Bernshtam 1951). To date, 21 runic inscriptions are known in Yakutia and the Upper Lena river basin including those located on the rock panels (Levin 2014).

International Perspectives

Although the rock art of Yakutia has not attracted much attention from foreign scholars, it may be of interest for international teams of researchers. From global perspective, the rock art of Yakutia finds its counterparts in other regions of the Sub-Arctic zone, for instance, in Scandinavia and the Canadian Shield, and methodological frameworks developed there can be applied to the Yakutian rock art. There are other research questions which can be approached from international perspective, as an example, rock art of Yakutia has been engaged in international research on shamanic themes in rock art (Devlet 2001; Rozwadowski 2014, 2017b).

Future Directions

As in many parts of the world, the most salient issue related to rock art is the problem of its conservation and preservation. Already one of the first explorers in Yakutia, A.A.Savin, who surveyed the Middle Lena basin in 1939, noted the poor condition of the rock art and described many cases where local people destroyed sites either to use the paint as a cure for diseases or to fight pagan beliefs. He pointed out that the limestone rocks constantly collapsed due to their fragile structure. Many outstanding rock art sites have been badly damaged by vandalism since then, and rock art sites of Yakutia are particularly exposed to erosion. Even though there are examples of sites in Siberia well preserved and managed due to endeavors of passionate researchers and amateurs (e.g., Oglahkty in Khakasia), no policy exists in Russia specifically devoted to look after rock art. The problem of managing rock art sites along with other archaeological sites is complicated by insufficient number of professional archaeologists in such large region as Yakutia. The second most important issue is the chronology of rock art (Rozwadowski 2017a). No

chronometric and scientific techniques have been applied, and the existing models need reconsideration based on the methods available today. As such, the rock art of Yakutia has a strong potential as an open field for various methodological approaches.

Rock Art Recording Methods: From Traditional to Digital

Inés Domingo Sanz
Departament de Prehistòria, Història Antiga i Arqueologia, ICREA/Universitat de Barcelona/SERP, Barcelona, Spain

Introduction

In the twenty-first century, accurate, integral, and noninvasive documentation of rock art has become a priority among researchers and cultural heritage managers, given the fragility of this cultural heritage which is subject to continuous environmental and human threats.

Today the documentation of rock art should meet multiple aims. Along with its main role as a research tool, rock art recordings are essential in monitoring the processes of degradation affecting rock art assemblages in the short, medium, and long term.

Furthermore, these documents are also significant as vehicles for scientific and, more importantly, public dissemination of the art, necessary to raise public awareness of the value of this heritage as a long-term conservation strategy to guarantee the preservation of this heritage resource for current and future generations.

Definition

By rock art recording, we refer to any form of visual documentation of the works of art and their spatial location, by means of photographs (analogical or digital), illustrations (drawings and/or tracings, traditional, or digital), and 3D real or virtual models. These documents are produced to record the formal and technical characteristics of the rock art, including the individual motifs (its shape, color, texture, technique, and conservation state), the spatial relations with the other motifs and the rock surface (including superimpositions), and the location within the site and the natural (Fig. 1) and cultural context.

Rock Art Recording Methods: From Traditional to Digital, Fig. 1 Location of El Carche Levantine rock art site (Jalance, Spain). (Photo I. Domingo)

Rock art recordings are permanent scientific records capturing the state of the art at a specific point in time. Since rock art is a fragile heritage and unfortunately, it is progressively degrading, rock art recordings are of great heritage value. Thus, they have to be accurate, avoid ideal reconstructions (even though they may be of use later on to facilitate public interpretations), and include a reference to the scale of the motifs recorded.

Two-dimensional recordings (either photographs or illustrations) usually capture one of the hundreds of point of views from where the work of art can be seen, with a general preference for the frontal (orthogonal) view to each motif to reduce perspective distortion. Three-dimensional models (real or virtual) usually provide a more realistic volumetric reproduction of the art complexes, and thus a more realistic volumetric approach to the sites themselves at a specific point in time.

Historical Background

Current rock art recording methods are the legacy of over a 100 years of experimentation leading to a gradual refinement of methods to obtain as complete and accurate working documents as possible, while minimizing the direct impact on the art and the rock surface.

Since the advent of photography, this recording system has been considered the most objective rock art recording method, because of its capacity to reproduce reality with great fidelity. This capacity to provide a controlled picture of the art clearly responds to the principle of scientific rigor required by any archaeological work. Although photography is not exempt from metric inaccuracies caused by lighting conditions, perspective, and/or lens distortion, today both forms of metric distortion can be minimized with different software (e.g., rdf) and with the use of digital calibrated cameras (Domingo et al. 2013).

In the initial stages of rock art research, photography was in its infancy and its use in the underground was problematic because of little available light. In this context, hand drawings and tracings became the main tool for rock art recording and dissemination. Decades later, and despite the great advances in photography, tracings retain their value as a primary rock art recording method because of their capacity to facilitate motif identification, especially when motifs are faded or part of complex superpositions. Thus, tracings consolidated as a technical tool for rock art interpretation, whose main role is to facilitate the reading of the rock art motifs and to be used for scientific and public dissemination and research (Aujoulat 1987, 1993).

The times have long gone when hand drawings, water colors, and pastels produced by researchers, artists, and illustrators, such as Breuil, Porcar, Cabré, Benitez-Mellado, to name some, were used as evidence of the first findings at the early stages of the twentieth century (Aujoulat 1987; Moneva 1993; Tosello and Fritz 2007). But hand drawings have not been completely excluded from the documentation process, and still play an important role in its initial stages. An initial hand sketching of the panels including the location and numbering of all the remaining motifs provides a good first understanding on how the panel works. And this first approach is necessary to plan the systematic recording of the site.

Continuous advances in research and the interest in answering new questions from the study of rock art led to the need for more accurate formal and metric documents than those obtained from hand drawings. Progressive new developments resulted in a gradual improvement of the results. These new methods can be classified into two main categories: direct recording methods and indirect recording methods.

Direct tracing or *contact tracing* is probably the most widespread rock art recording technique worldwide, among the direct recording methods.

This method involves placing a transparent paper on the decorated surface, on which motifs are identified and traced using a permanent ink pen. Different colors can be used to identify different motifs or to code different types of information related to the motifs (e.g., shapes, techniques, etc.) and the rock surface (e.g., cracks, bumps, etc.). The relatively good adaptability of the cellophane or polythene to the irregularities of the rock surface improved the resulting reproductions both from the metric and the formal points of view. However, one of the most significant disadvantages of this method is the direct impact on the fragile rock surfaces and the motifs, which could accelerate the degradation processes. The location of the tracing paper between the recorder and the motifs obstructing the direct view of the art also hinders the recording process. One last disadvantage is the problematic transformation of the resulting real size tracings, usually of large dimensions, into manageable scales for research and publication, since large format scanners would be needed. In most countries, a permit from the regulatory authority is required for this practice.

Another widespread form of direct recording is the rubbing of engravings. It consists of laying a thin paper on top of the engraved surface and rubbing carbon paper on top to obtain a reproduction of the engraving. As in the previous methods, this technique impacts directly on the rock surface, so the use of other noninvasive methods is more recommended.

Indirect recording methods include, apart from analogical and digital photography, a variety of indirect ways of tracing:

- *Tracing produced using a frame*, with several options based on the use of a rigid or semirigid structure placed at a certain distance from the rock surface to avoid direct contact (Lorblanchet 1993a, b). The main weakness of this method is the struggle to adapt these structures to the irregular surfaces characteristic of most of the rock art sites, with consequent deformation of the final results.
- Tracing on analogue photographs, which involves tracing the motifs on transparent paper placed directly on the photograph. The use of orthogonal photographs, digital calibrated cameras, and specific software (as mentioned before) to correct metric distortion minimizes distortions generated by the camera and the transformation of 3D into 2D surfaces (Domingo et al. 2013). This also applies to the next two indirect recording methods.
- Tracing on slide, in which the projected motif is traced using tracing paper.
- Digital tracings, which are the digital version of the *tracing on photographs* method, are produced using digital image enhancement and processing software. Rock art paintings are generally "traced" from digital photographs using color selection tools to individualize the pigment from the rock surface (Domingo and López-Montalvo 2002). Rock engravings are mostly drawn with several drawing tools on top of the digital photographs taken using oblique light in dark conditions.

Key Issues/Current Debates

Certainly, the quantum leap in rock art recording methods came in the 1990s, with the widespread use of new digital technologies. Gradual technological improvements have broadened the range of rock art recording methods available. They have also provided the tools to facilitate a continuous review, correction, and update of the rock art recordings.

Several software (Adobe Photoshop, Gimp, Corel Photo Paint, and so forth) and specialized plugins (DStretch for ImageJ) for digital image enhancement and processing are used worldwide to facilitate rock art visualization (Clog et al. 2000; David et al. 2001; Brady and Gunn 2012) (Fig. 2). These photo processing software programs have also replaced traditional tracing methods. They provide the tools for digitally drawing rock engravings and to produce digital "tracings" of rock paintings using a range of color selection and drawing tools (magic wand tool and color range tools) (Vicent et al. 1996; Cacho and Gálvez 1999; Clog et al. 2000; Domingo and López-Montalvo 2002; Rüther 2007; Martínez-Bea 2009; Cassen and Robin 2010; Domingo et al. 2013; etc).

The traced motifs can easily be scaled, assembled into panels (Fig. 3), divided into stylistic phases or periods, or used individually for formal comparison with other motifs, and so forth.

The digital era has also provided sophisticated equipment and software to produce virtual 3D models of rock art sites (digital photogrammetry, laser scanner, and so forth) (Robson et al. 2001; Lerma et al. 2010; Ortiz et al. 2010, etc). These models provide a unique approach to the 3D quality of rock art, which is key to understand the art in context (location in the panels, use of the rock surface, and so forth) and to show the multiple perspectives from where the audience can visualize the art.

However, when the rock art panels are faded or the motifs are difficult to identify due to complex superpositions, photorealistic models are insufficient to identify them (Fig. 4). Thus, recent developments in rock art recording methods recommend the combination of photographs and tracings into the 3D models (Domingo et al. 2013), and the use of several layers within the files containing the 3D model, the photorealistic model, and the tracings to facilitate the reading of the art (Fig. 5).

Furthermore, the addition of old and new records into the 3D model will allow the creation of 4D models displaying changes in the site

Rock Art Recording Methods: From Traditional to Digital, Fig. 2 Human figure with bow and arrows from El Carche site (Jalance, Spain). Digital enhancement using Dstretch facilitates the visualization of details. Scaled digital tracing produced with Photoshop color selection tools

through time. These models could be of great value in assessing future rates of degradation processes.

While 2D rock art recording methods are currently the most widely used, the value of 3D models for the study, long-term digital preservation, and dissemination of rock art is widely accepted. Nevertheless, the high costs of high-quality reproductions, the storage limitations, and the virtual dissemination of the models are still problematic and will have to be solved in the near future, if 3D and 4D methods are to become the standard methods of rock art recording.

Future Directions

More than a 100 years of rock art discoveries and research have generated a significant amount of visual records (photographs, illustrations, real and virtual models, and so forth) that unfortunately are so dispersed among institutions, publications, and private hands that, as rock art, they are in danger of disappearing. In the past, and still in the present, a significant number of these records have been in

Rock Art Recording Methods: From Traditional to Digital, Fig. 3 Digital tracing showing the relationship of the human figure with the motifs located in the surroundings

Rock Art Recording Methods: From Traditional to Digital, Fig. 4 Snapshot of the photorealistic 3D model of El Carche site, with the location of the human figure. (Project HAR2011–25440, ICREA/UB/SERP. Produced by GIFLE)

the hands of the people who produced them, and thus, they have disappeared together with their authors. But the heritage value of these records requires guaranteeing their long-term preservation, thus, the need to create official repositories (real or virtual) at stable institutions, to guarantee their conservation, and perpetuate their value.

As new technologies develop, new improvements in each step of the rock art recording process will be introduced. This will include reducing subjectivity and direct impact on the art, increasing the accuracy of the records, or reducing the size of the files to facilitate virtual storage and dissemination, to name a few. At the moment, 4D models are with no doubt the most immediate future for rock art recording methods, but certainly, the digital era still hides new unimaginable surprises that will benefit the discipline.

Rock Art Sites: Management and Conservation

Johannes H. N. Loubser
Stratum Unlimited, LLC, Johns Creek, GA, USA
Rock Art Research Institute at the University of the Witwatersrand, Johannesburg, South Africa

Introduction

Concomitant with an increase in site accessibility, digital availability of information, and concern by traditional stakeholders is an increase in the need for explicit management plans, thorough condition assessments, and, whenever necessary, hands-on conservation and maintenance of rock art sites. Significance values concerning rock art sites tend to vary; whereas traditional stakeholders normally value the spiritual aspects of places with rock art, researchers typically look for material samples suitable for physical analysis and dating, and public visitors and tourists mostly look for any destination that they expect to be aesthetically pleasing. Interactions by traditionalists, academics, and the visiting public with the rock surface, albeit in different ways and to different degrees, are adversely affecting the longevity of the rock art. Being fixed to the surrounding terrain on relatively hard and durable material, art on rock constitutes places that tend to survive the ravages of time. But because painted or engraved marks on the rock are vulnerable to agents of natural and cultural destruction, site custodians, such as private landowners and land-managing agencies, often look for ways to slow the clock of decay, while a few others, such as visitors and traditional users of sites, view decay as part of the natural order. Whichever view prevails, it remains important to devise ways in which rock art sites are managed and conserved to best suit the needs of the most prominent stakeholders and/or surrounding communities. In the eyes of both landowners/managers and traditional users, rock art sites suffer negatively when they are arbitrarily "managed" through the unpredictable actions of outside visitors with no long-term or vested interests in those sites and effected communities.

Definition

The most frequently found examples of rock art include painted or drawn pictographs (i.e., where naturally colored clays are applied as ground-up powder mixed with water and a binding medium or applied directly with a lump of clay or charcoal) and engraved or pecked petroglyphs (i.e., where natural surfaces are engraved, incised, or pecked with a sharp implement, typically a hard rock). Hands-on graffiti removal from rock surfaces has shown that water is an essential material to produce lasting pictographs and petroglyphs. By adding water to pigment powder, colorants penetrate the pores and interstices in the rock surface, hence creating a tighter physical bond between pigment and rock than when applied dry. By adding water to the rock surface, dust particles created by engraving, incising, and pecking speed up the production of petroglyphs and allow for deeper and wider lines. Without the addition of water during pictograph and petroglyph production, the images would not survive long, especially in open air settings. Surface accretions, such as silica-rich skins, that cover many pictographs, create a protective layer. Knowing that pictographs and petroglyphs are part of the rock surface, rock art is better referred to as "art *in* the rock" instead of "art *on* the rock." Pictographs are most frequently found in dark zone caves (e.g., mostly in the form of dry-applied drawings in the Paleolithic-aged Franco-Cantabrian region or Archaic to Mississippian ones in the southeastern United States), comparatively shallow caves and rock shelters (e.g., mostly in the form of wet-applied paintings in Middle to Late Stone Age San sites in Africa, various Native American sites in the Americas, and Aboriginal sites in Australasia), or where boulders create rock overhangs. Petroglyphs are more frequently found in rock shelters (e.g., Africa, Australia, and the Caribbean), rock pavements (e.g., coastal Scandinavia), or against

boulders. Petroglyphs might be attached to the parent rock or can be on boulders inserted into the ground surface, such as along the prehistoric ball courts of the Taíno peoples in the Caribbean. Proper management of rock art sites includes recommending proactive guidelines concerning acceptable recording, sampling, visitor behavior and numbers, interpretive infrastructure, and conservation and maintenance. Hands-on maintenance and conservation are important components of rock art site management. Actions range from keeping the site free of litter and deleterious agents through regular monitoring through to removing graffiti. A thorough assessment of a site's physical condition helps to determine major conservation problems as well as potential threats to visitors' safety. Determining what section of the population a site should be opened to and/or catered for will usually be based on understanding a site's significance values. Knowledge of the management history and infrastructure of a place helps with decision regarding what has worked in the past and what is likely to fail in the future. Sustainability is also a key concept; management infrastructure and conservation measures should not only be minimalist and repeatable but also compatible with natural materials and prevailing significance values.

Key Issues/Current Debates/Future Directions/Examples

Rock art is found in almost every corner of the globe where people have lived. Antarctica was the only continent without rock art up until the first documented landing of humans in around 1821. Knowing that most rock art we see today is old (currently the oldest dates range between 40,000 and 70,000 years ago), they are essentially non-renewable resources; in the absence of their original makers, nothing can recreate rock art panels that have been severely damaged or destroyed. The non-renewability of rock art is one important aspect that makes preventative management so important, especially in the light of increasing visitation by uninformed people. It is important to realize that rock art that has survived two millennia can be destroyed in less than two minutes of frenzied vandalism. Ways to prevent interference with rock art panels are not clear-cut and have given rise to various debates, both between and within divergent interest groups.

The location and shape of rock art panels are important, bearing in mind that certain locales and rock surfaces are chosen over neighboring ones that appear at first glance to be equally suitable. Every effort should accordingly be made to conserve rock art sites in their original location. Often this becomes impossible, where infrastructure critical to the livelihoods of local communities is constructed: in these situations, the best alternative can be to carefully remove and relocate the panels to the interpretive setting of the closest viable museum. Sometimes, such as in the Côa River Valley area of northeastern Portugal, academic and public outcry can be sufficiently loud to stop dam construction activities so that significant rock art sites can be preserved in place.

There is a site in Puerto Rico, which must remain anonymous to prevent looting, where excavated petroglyph boulders have been reburied, because the condition assessment results indicate that the soil cover provided the best preservation matrix for the 1,000-year-old carved imagery. But the preservation afforded by the soil was not the only reason for this conservation decision: all stakeholders agreed that the spiritual and research significance of the boulders overrode the need for display to outside visitors.

Rock art sites often have ongoing importance to many direct descendants of the makers or by people historically associated with them, most vocally in portions of Australia and North America. Rock art sites are undoubtedly important to direct descendants and related traditional users in other part of the world, but these peoples' voices have yet to be heard in an equal degree. Traditional practitioners who visit rock art sites tend to do so without fanfare, so what these people do at sites is difficult to determine. Telltale signs of visitation within some rock shelters in the Americas are the application of traditional-looking pigment on top of recent flake scars. In

portions of western North America and Australia, the need for repainting or overpainting existing imagery has become topics of intense debate, including among traditionalists. Lasting solutions are hard to come by, one reason being that even within a single community, there can be a division between those who support painting and others who oppose it; rock art sites are part of a wider web of contested sociopolitical and economic relations.

In portions of subequatorial Africa, Bantu-speaking agriculturalists are using the rock painting sites of their hunting and gathering predecessors for ritual sacrifices to their ancestral spirits. These rituals, which include spattering sorghum beer onto old paintings and vigorous dancing, generate dust that settles on and adheres to the panels, which is deleterious to the ongoing visibility and integrity of the imagery. However, in terms of community concerns and support, it would be difficult, and indeed unethical, for authorities to suppress this long-standing practice. Does the conservation of this imagery have a greater value than the ongoing traditional uses of the imagery by local people? The Kondoa Irangi rock painting sites in Tanzania have great significance for locals selling their goods and services to tourists as well as for local ritual practitioners. As in other parts of the world, the management issues are not straightforward, since communities seldom represent a single interest group or speak with one voice.

The use of the very term "rock art" has been questioned by traditional stakeholders. Both Australian Aborigines and Native American Indians, for example, have requested that terms such as rock imagery, rock pictures, or rock writing be used instead. Their reason for this request is not so much that they deny the aesthetic quality of the paintings or engravings but rather that the place and its associated narrative and ongoing use by far override artistic significance. This is something that agencies responsible for the management of such sites should bear in mind; interpretation and presentation to the visiting public should emphasize, where justified and relevant, that locales with paintings and engravings are significant for reasons other than artistic merit or aesthetic appeal. Nonetheless, the word rock art is still recognized and used by most people.

When dealing with rock art sites, it may be helpful to realize that among most traditional cultures, the division between sacred and profane is not as rigid as it is among post-Industrial peoples. For example, Bantu-speaking women who collect plants from below drip lines in rock shelters insist that the leaves or fruits are food provided by ancestral spirits residing immediately below the surface. Some Blackfoot Plains Indians used to incise depictions of their everyday exploits, such as during raids or hunting expeditions, as if these were intertwined with their vision quest experiences. Knowing that the divide between practical and spiritual is blurred, it may be rushing to judgment labeling certain sites religious and others secular.

There is no blanket solution that covers all rock art-related management and conservation issues. Although rock types, weather systems, biota, and sociocultural formations share many properties, they combine in unique ways, reminiscent of fingerprints. Due to the unique characteristics of each site and panels within those sites, it is important to assess and manage these on their own terms.

One common reaction among land managers is to close rock art sites for public visitation. While this solution may work for constricted sites that are sensitive to slight changes in air quality or inadvertent physical abrasion of surfaces along narrow passages and low ceilings, particularly within dark zone caves, it is more difficult to close to the public spacious rock shelters that are highly visible and well known. When properly managed, with the necessary protective and interpretive infrastructure in place, rock art sites that show signs of custodial care and attract many visitors tend to suffer less from vandalism.

Successful infrastructural changes at rock art sites in countries such as Australia include removable boardwalks with low handrails and mounted interpretive panels that help visitors identify motifs. Sites opened to the public in this fashion help draw visitors away from nearby sites that are

physically more susceptible to visitor-induced damage. Visitor books, kept in boxes that are mounted on pedestals near the entrance to many sites in the United States, serve many functions, including recording the numbers, names, addresses, and comments of visitors as well as providing basic interpretations of the site and its rock art. However, when not properly maintained, the neglected appearance of rock art sites may increase the chances of vandalism. In drier areas, structures such as wooden boardwalks may increase chances of fire damage and sand accumulation at sites. To reduce incidences of unforeseen damage, it is preferable that site managers only make minimal infrastructural additions to a site.

Generally, sites farther from car parks tend to be vandalized less than those in close proximity to motorized vehicle access. Once graffiti appears at a site, it tends to beget more graffiti. For this and other reasons, such as increasingly used enamel-based spray paints bonding with the rock through time, it is important to remove graffiti as soon as possible (Fig. 1). Specialized and experienced individuals, who know the rock art of the area, should be hired to do graffiti removal, as often original images have accidentally been removed by well-meaning conservators that have no knowledge of rock art. It moreover helps to consult all interested parties prior to graffiti removal, bearing in mind that some names and dates may have historic and sentimental value to people from the local area. But knowing that even the best managed sites can be vandalized, well-paced motion-detection cameras can help monitor sites and catch vandals in action. Proper walking surfaces, barriers, and signage are essential to create a sufficiently wide protective space between visitors and the rock art surface. Without monitoring and properly designated viewing areas, graffiti is likely to be recurrent and costly to mitigate.

Rock Art Sites: Management and Conservation, Fig. 1 Example of spray paint graffiti removal at a pictograph site near Las Vegas. (**a**) Graffiti spray paint before removal. (**b**) Graffiti spray paint after removal

Correct conservation and management decisions depend a lot on good background information, such as old photographs, maps, and descriptions of rock art sites and the surrounding terrain. When rock art specialists consult such archival sources, it becomes possible to reconstruct a history of site condition, visitation, and land-use. Reconstruction of this kind often helps rock art specialists identify critical changes in visitation and/or land-use that resulted in damage to the rock support and imagery. But historic photographs can also reveal that no change has occurred in the recent past and that observed "damage" to sites has a very long gestation.

Practiced properly, rock art management and conservation is a holistic undertaking; knowledge of both the physical makeup of sites and human context is vital. Where past and present uses and significances of rock art sites can be confidently reconstructed through archaeological and ethnographic research, it is important to include this knowledge when making decisions about the best ways to interpret and present sites to the visiting public. When ethnohistoric background research shows that distant features, such as mountains, rivers, or abandoned towns, are conceptually related to rock art sites, it is important to take this into account and preserve the integrity of the views to these other landscape features whenever possible.

Rock Art, Forms of

Denis Vialou
Muséum National d'Histoire Naturelle, Paris, France

Introduction

The most general and commonly used term, "prehistoric art," refers to forms produced on diverse mediums by human who lived in distinct prehistoric periods, in particular region of the world (Lorblanchet 1999; White 2003; Vialou 2004, 2006).

Definition

It should be understood from the outset that these forms, commonly called pictures or images, are those that have had the capacity to be preserved. Thus, only the forms inscribed in lasting materials and organic mediums, which are resistant to multiple natural alterations and changes in the environment and climate, testify to the symbolic-artistic behavior of prehistoric peoples: their voice and songs have gone; their dances have disappeared in the fleeting animated moments.

Other examples of symbolic behavior have survived from prehistoric times, for example, unusual objects gathered and brought inside habitations. But it is above all the burials of men, women, and children that attest, for nearly 100,000 years, to a metaphysics of life and death, whose religions have been the distant heirs, about tens of thousands of years ago in some scattered crucible of ancient civilizations.

From various prehistoric cultures and from various eras dating back more than 100,000 years, graphic representations have reached us (lines incised and sometimes painted – more rarely preserved) on portable or manipulable and hence transportable mediums, decorated weapons, ornamental objects for the body, and sculptured objects. These *portable* forms, as they are often called, sometimes form considerable groups alongside rock or parietal forms; the best example is given by "Paleolithic art" in Europe during the last thirty millennia of the last ice age (Leroi-Gourhan and Delluc 1995; Anati 2003; González Sainz et al. 2003).

The words "wall" and "rock" describe immobile monumental forms, sometimes of monumental proportions. However, the majority of them fall within the gestural space of their authors; a good portion of them are also small, within the size of the palm, and some even smaller.

The adjective *parietal* commonly used in anatomy, is the most appropriate term for cave walls. The adjective *rupestre* in Romance languages, refers to media formed by rocks or boulders. It is thus less generic than the adjective *pariétal*. In the English language, *rock art* corresponds to *rupestre*, whereas *cave art* refers to art on the walls of caves: it is thus equivalent to the French qualifier *parietal*, specifically applied to Paleolithic cave art and in contrast to portable art. The use of the word *rupestre* has become dominant internationally for designating prehistoric representations on rocky mediums encompassing all of their geological and morphological diversity.

Key Issues/Current Debates/Future Directions/Examples

The Nature of Prehistoric Representations

The concept of *representation* here concerns the image or form in order to emphasize the psychological and semantic dimensions of the relationships established by each one with the outside world: the representation of things or beings is an invention or a personal (psyche/state of mind) and collective (social) construction engaging the meaning that is assigned to them through naming, seeing, or manipulating them; for example, the representation of a weapon can be formulated in various figures (or images), a dagger, a bow. The representation of violence can be expressed visually in a thousand ways (forms), combat, fight, tortured face. . .. The representation of sexuality engages in a similar way the individual and the group, with even more obviously an unconscious part, both underlying the representation expressed

on the wall and the representation in the depths of *moi*. In fact, most prehistoric rock iconography, of varied times and locations, culturally independent, shows treatment, figurative or partially codified, of sexuality: this denotes simultaneously the universal and the cultural side.

The systems of representations shaped by the brain, including the most basic (literally), that is, the language born in infancy, integrate multiple forms of abstraction, the preferred tools of social communication based on intellect. The graphic expression of abstractions is based on codes, socially created and recognized. Prehistoric rock iconography has undoubtedly codified expressions of abstraction, but it is impossible to decode those that may be considered in this way; as examples, it is probable to regard concentric circles or rows of dashes as counting systems: mathematic codifications, such as I + I = II, are made up of graphical representations which are frequent in many rock assemblages. Symbolic activity, totally intrinsic to humans, constantly produces mental images during sleep as well as during wakefulness. Recalling what F. Goya was saying, as an epigraph to his Caprices that reason asleep produces monsters, it appears that many rock art presentations (according to different cultures) fall under these symbolic productions, conscious and unconscious: half-animal-half-human beings, scary monsters, etc. That such myth claiming that the Tapir was the creator of the world comes under the same expressive power; such rock art representation of an antelope, snake, or mammoth could take the same role in telling the story, symbolically the most reliably true of such group.

The graphic expression of symbols which are thought about, spoken, and exchanged within a group for a limited time (over one or many generations) is not only linked to the real world (or considered as such, whenever it involves an animal or a human figure). Christians have the cross and the sign of the cross, the Magdalenians from Perigord 14,000–15,000 years ago had the tectiform sign (in the shape of a roof hut), while those, more or less contemporary, of the Cantabrian region symbolically used quadrilaterals with internal partitioning. Visual symbolization (graphic for rock art) passes easily through the geometric abstraction. For example, we could mention the most banal angular sign that can be seen, a V: it can symbolize an injury when it is placed on the side of an animal and an arrowhead when placed over a linear axis (Fig. 1) or even signify hope for an expected victory, drawn by the two raised fingers of a political figure.

Abstract rock art representations, most commonly designated by the semantically neutral term *sign*, abound in some rock art cultures, like on the walls of Paleolithic caves in western Europe or in the rockshelters of the central

Rock Art, Forms of, Fig. 1 Niaux cave (Ariège, France) buffalos, horses, and symbols Magdalenian. Cl. A and D. Vialou

Brazilian plateau, and are (more or less) absent in others, like in the rockshelters of Tassili n'Ajjer (Algerian Sahara) or in Arnhem Land (Australia).

Anthroposocial Origins of Prehistoric Representations

Whether figurative or abstract, rock (and portable) art representations are rooted in the individual and collective consciousness of prehistoric peoples who produced them, from early hunter-gatherers to later producers in various parts of the world. The domestication of animal species did not suppress the creativity of rock art!

The first known graphic representations, such as the incisions systematically made into portable mediums, which come from the occupation of habitats recently excavated in southern Africa, are dated more than a hundred thousand years ago (Henshilwood and d'Errico 2011). The oldest rock art representations of signs, combining figurative representations, animals and humans, and geometric or abstract, are dated between 30,000 and 40,000 years (Aurignacian art in Paleolithic Europe).

These most distant origins of representations made in and on durable media are part of the phylogeny of Sapiens (*lato sensu*) and its diaspora throughout the world, which is currently being debated (Otte 2010). The ability to produce these forms, graphically materialized, is not attested before Sapiens and/or contemporary human lineages, which are genetically close in various regions, such as the Neanderthals in the Middle East and Europe. It becomes apparent between, on the one hand, the production of graphic images and the evolution of human lineages and, on the other hand, the production of complex parietal settings, which bring into play figurative expressions and abstract expression of the evolution of Sapiens.

Diverse and multiple symbolic behaviors evidently existed prior to graphic manifestations. But the emergence of these in association with the development of the Sapiens lineage indicates that it pertains to it: there is indeed a *before* the forms and an *after* the prehistoric forms, which connects us (all Sapiens) to an evolutive modernity, specific to prehistoric Sapiens. The construction of these graphic forms, driven by the representation of the world, emerges from and in the brain (Vialou and Vilhena Vialou 2005). The most notable evolutionary trait of the Sapiens compared to earlier types of Homo is that of cerebral development. This trend is paleontologically visible with the progressive verticalization of the face of unearthed fossils. The frontal lobe, that is, the cortical area directly involved in the development of systems of representation, benefits from an increase (and more complex) that is crucial for the maturation of symbolic and technical relationships with others. The emergence of prehistoric art is in parallel to these new techniques of fabricating tools and weapons in bone and stone and of new modes of economic acquisition and exploitation of natural resources. Obviously, the systems of graphic representation were born simultaneously and correspondingly within the brain and the Sapiens societies, notably anatomically modern humans from prehistory, over the past 40,000 years.

The Universality of Prehistoric Representations

Prehistoric representations present universal characteristics, derived from their anthropogenic origin, expressed in graphic and artistic behaviors.

The techniques of graphic expression on walls are remarkably uniform. Three major categories can be differentiated, each one offering secondary variations: engravings, drawings, and paintings (Vialou 2003).

What is commonly called *engravings* covers all forms of incisions made with instruments, organic and mineral, harder than the media. One (or more) finger may be used as a natural (and spontaneous) instrument to leave its mark on a wall that is sufficiently soft, such as the mondmilchs in limestone caves. These digital prints, usually more or less long meandering maze lines (the "macaroni"), express a direct, almost fleshy relationship of the body with the material which develops since childhood with the footprints that are left or made involuntary or voluntary in the sand of a river or the beach. But one's touch on a wall, even if superficial, retains

its trace, in contrast to the one done in sand or mud. Bones or pieces of wood are also used for equally tracing quite large parietal marks removing a notable quantity of media material.

The use of hard stone tools (flint, quartz, quartzite, etc.) enabled people to carve, pound, or peck on rocky walls that are themselves resistant. A wide range of strokes are found ranging from ultrafine incisions (less than 1 mm) to deep grooves (several cm wide and deep). Often these deep grooves have been polished by intensive rubbing bringing into play other stone tools and granular abrasives (sand). The use of percussion tools, by hammering the medium, has given pecked linear grooves or more or less deeply pounded surfaces.

The removal of material *on* a medium also represents the achievement of surfaces in *relief on* a rock surface: either by making a peripheral withdrawal of the material to raise a surface in the center or by making localized withdrawals within the rocky surface that is worked to represent, for example, the anatomical volumes of an animal. Finally, according to the thickness of the material removed, the representation obtained appears in *bas-relief*, eventually in *semi-relief*, but almost never in *high relief* (as is found on historic monuments).

Whereas engraved (and pecked) representations cover the totality of prehistoric thematic fields, representations in relief (raised up and hollowed) are (almost) exclusively figurative, namely, animals and much less often humans. Representations in relief are rare and indeed absent from most rock art sites, regardless of their chronological position. By contrast, engraved representations are generally the most common and found in all rock art in the world. We can explain the dominance in the engraving technique by two factors of which it is difficult to evaluate the reciprocal influence: the choice of the technique as such, which is proven *a contrario* by the absence of engravings in the rocky regions. These choices may have been based on ideological, artistic, or simply technical motifs. The second factor is that of conservation compared with drawings or paintings. Engravings have a better and longer resistance against the multiple effects of weather and geochemical modifications of rocky surface that are affected by them.

What is commonly known as *paintings* covers all inputs of coloring materials on the different medium. The coloring materials of natural minerals, hematite, ocher, manganese, kaolin, etc., taken from the surroundings landscape (sometimes many kms away), have been used as they are found or are well prepared: thus, for example, small flat hematite pebbles (red iron oxides) were directly used as pencils to draw on walls (shorter or longer linear marks); the same types of mineral pigments were reduced into a powder and mixed with a liquid (most commonly water): the paint thus obtained, more or less liquid or as a paste, as desired, is then deposited on the media in the form of linear marks, that is to say, lines or colored tracks; on the one hand, we are dealing with drawings and, on the other, with flat color paintings (solid infill), with all the possible variations in between these two extremes of graphic-pictorial expression.

The *thematic categories* of prehistoric rock art characterize both its universality and its precedence on the global chronological scale compared to historic arts. Figurative representations, abstract representations, and undetermined representations constitute the three thematic categories of rock art, on the five continents, with variations of course, dominant or absent, according to different regions and eras.

The *indeterminate* representations, which occur in varied quantities in different iconographies, include numerous lines or spots, small or large, and shapeless and undistinguishable. Indeterminate representations seem to participate in both the thematic expression of the devices and their structure chart (like prepared backgrounds).

Abstract representations, geometric shapes that are more or less simple (signs) or complex (motifs), are, on the one hand, more numerous than figurative ones, and, on the other hand, much smaller than these (Figs. 2 and 3). Whether they result from the graphic abstraction process or from the graphic process of symbolic expression, they escape immediate identification. They distinguish prehistoric rock art from the historic arts. However, the emergence, only recently, of

abstraction within Western graphic (and fine) arts raises questions about what could be conceptual affinities in terms of expressive modality that deliberately put aside recognizable reality.

Figurative representations, more spectacular than the others, make people believe, within the imagery of our societies of Western culture, that prehistoric art is an art of animals. Indeed, animal representations are common and numerous: they include wild fauna – hunted or fished – but also domesticated species in rock iconography among Neolithic societies who have domesticated livestock, for example, cattle herds painted in shelters of Tassili n'Ajjer (Fig. 4). Human representations

Rock Art, Forms of, Fig. 4 Shelter 6 of Sefar, Tassili N'Ajjer, Algerian Sahara. Domesticated bovine herd. Holocene Period. Cl. A and D. Vialou

are frequent, sometimes outnumbering animal representations.

This category also includes, but in a very uneven and inconsistent fashion, representations of weapons, clothing, or more rarely with other material objects like gourds or even constructions like fences or huts. There is a near total absence of the plant world and landscapes. In addition, the stylistic treatment of human figures on rock (as well as on portable mediums) is different from animal representations to the extent that figurative, naturalist realism is almost never applied to them. In this, they differ radically from realistic human representations that occur, here and there, only with history.

Media and Parietal Setups

The chosen *media* guided, by their structures and dimensions, the conception and the construction of parietal setups. In some areas, hardened soil, such as the laterite soils of the tropics, offered sometimes immense surfaces: the representations, more often pecked than incised, unfold themselves in all directions, in contrast to that which occurs on vertical or tilted walls, naturally oriented (top-down and left-right). Sometimes these representations, figurative or not, are very large, because they were produced by moving.

The rocks themselves give the dimensions and the composition of parietal setups: there may be blocks of average size (from a few tens of cm to 1 m) offering one or more faces to engravers. There are the rocks exposed on the surface of streams: rock art in the Amazon is replete with engraved rocks, often with geometric motives such as spirals. There are also engraved rocks scattered, or alternatively, showing on the surface in their hundreds on plateaus, such as in South Africa (Magaliesberg), the sides of valleys, for example, Foz Côa (Portugal), valleys close to Santa Fe (New Mexico), and also in high Alpine valleys like that of Mont Bego. Similarly, rocky chaos on steep hillsides has been filled by thousands of representations, in the Dampier Archipelago (Australia), for example. Powerful rocks or bulging rocky outcrops over several meters were chosen to depict representations reaching impressive proportions.

Walls at the foot of cliffs, glacis on mountains, walls of rockshelters, or the porches of underground cavities were selectively chosen by prehistoric peoples to deploy their symbolic constructions according to the parietal setups responding to the rules of organization of the graphic space. The parietal space offered by rockshelters has morphological and topographical constants, whatever their secondary variations (small-large, high-low, wide-narrow, deep-dish), and these are crucial to the development of representations and their display. The space is oriented in three dimensions: a design space with high-low and left-right and, where required, the depth of

space constituted by the ceiling of the canopy, which can, accordingly, be laterally framed by one or two rocky walls, more or less perpendicular to those at the back of the shelter, normally chosen to accommodate the representations. These volumetric dimensions of the space available to those who came to perform representations or/and live there, temporarily or not, condition the parietal setups in shelters.

The *parietal setups* are normally done on the back wall of the shelter. The ceiling of the cave is more often ignored than not. The parietal setups on the wall of a cliff or a large rock, not sheltered, are oriented and structured like those at the back of the shelter. The graphic space most commonly attested is that of the manual field of the author, standing up: there are infinitely fewer representations placed below the knees and even less higher than the limit reached by outstretched arms.

The composition of parietal setups (regardless of their location) are based on three categories of spatial relations: the *juxtapositions* between two or more representations, on the same plan, for example, to simulate a line or a confrontation, or, on fragmented plans, as if the representations floated in space; more or less partial *superpositions* between two or more representations and according to the same variations of previous plans; and finally, the *interlocking* between two representations, which are even more rare. The symbols (and geometric motifs), being always (except in very rare exceptions) smaller than the animal figures, are more often interlocked than are the animals between them. Human representations, often reduced to small, simplified silhouettes, are regularly arranged in rows, in close juxtaposition; they are not frequently superimposed or interlocked with animals. The symbols have little effect on human representations by superposition and even less by interlocking: it is clear that there is like a disjunction between animals and humans in terms of their symbolic links, and this is true in the ensemble of prehistoric rock iconography.

Diversity of Prehistoric Representations

Prehistoric representations and their parietal setups offer an infinite number of special characteristics related to the diversity of cultures with which they identify.

Rock themes generate the dynamic of this inexhaustible diversity. The figurative themes play the most constant role in relation to the abstract theme, because they concern all rock art in the world, across various epochs.

The category of animal representations is obviously the first issue: indeed, in the rock setups in Africa, there exists a purely African fauna, for example, giraffes, tapirs in south America, echidna in Australia, or reindeer in Scandinavia. The animal species clearly characterize the environments in which they live and the climates which are linked to them. But their representations correspond to the choices made by the societies that produced them. The impact of economic behavior and social exploitation and the consumption of animals (hunting, fishing, scavenging, domestication, breeding) are real but uneven according to the societies and their rock iconography. Animal species, represented almost endlessly, in some contexts have been elevated to totems, to emblematic figures, we do not know, in any case representations entrusted with their own meaning. There are wonderful examples attesting to this: the eland in Bushman art in southern Africa (Fig. 5) and the barramundi in Arnhem Land (Fig. 6). Paleolithic representations show variations of animal representations allowing the identification of regional or local traits: we can take, for example, the representations of horses and bison, two species which are extensively represented by Magdalenian, of which the quantitative weights are different depending on the region, Cantabria, Pyrenees, and Dordogne. In other sites there are emphases on horses (in Ekain and Combarelles) or bison (in Altamira and Font-de-Gaume) (Leroi-Gourhan and Delluc 1995). In some cases fauna portrayed in rockshelters and rocks in the Sahara shows adaptation of societies to desertification with the progression of camelids, horses, and finally of Neolithic bovines.

Unlike animals, human representations could reflect a universal thematic unity, but their graphic treatment reveals their symbolic variability. These obviously discriminate the societies and cultures

that produced them, with clothes and jewelry (Fig. 7), weapons, and various objects. The most notable of the irreducible diversity of human representation comes from depictions of the naked body, whether it be distinctly gendered or not. It would be more precise to speak of *disfiguration* than figuration, as the symbolic value given to silhouettes and heads, face, and their profile is strong and often strays away from the real anatomy. Some ideologies, however, give clear figurative similarities without suggesting the least cultural kinship. This is clearly the case with bow hunters, more or less schematic, seen as spectacularly stepping over open space, legs fully extended, torsos bulging, and bow stretched forward, elegiac images of famous hunters (Figs. 5 and 8)!

The apparent convergence of basic geometric shapes explains the apparent uniformity of signs through a multitude of rock iconography: in fact, a point resembles a point, a double row of dashes is just like any other, concentric circles resemble concentric circles, etc. By contrast, the most complex symbols and motifs (repetitive or not), such

Rock Art, Forms of, Fig. 7 Tan Zoumaïtak Shelter, Tassili N'Ajjer, Algerian Sahara. Adorned and dressed characters. Holocene Period. Cl. A and D. Vialou

Rock Art, Forms of, Fig. 8 Shelter 23 de Sefar Tassili N'Ajjer, Sahara algérien. *Flying* bowmen. Holocene Period. Cl. A and D. Vialou

as reticulated rectangles or closed sinuous outlines internal fill-ups, are specific to their own region and period. Within the same rock region, culturally homogenous, the complex symbols and motifs belong to a single site or two or three neighboring sites: these topographic specificities offer the possibility to distinguish symbolic neighboring micro-territories sharing common traits and other individual ones relating to a single regional population. The spatial connections between symbols, between them and figurative representations, which frame the symbolic constructions of parietal setups, accentuate even more the cultural identities which they characterize in different ways.

At this level, we have reached the fundamental nature of prehistoric art and its major function, which is to reflect the most significant cultural

traits of societies, in an aesthetic and symbolic dimension extremely elaborated. Art and society have cross-fertilized in this way since modern humans were created in all their universality.

Rock Art, Semiotics and Meaning of

Álvaro Rodrigo Martel
Instituto de Arqueología y Museo, Universidad Nacional de Tucumán, San Miguel de Tucumán, Argentina
Instituto Superior de Estudios Sociales (ISES), CONICET, San Miguel de Tucumán, Argentina

Introduction

The problem of the meaning of past societies' material culture has been one of the main concerns of archaeology since its origins as a scientific discipline. Such interest in the meaning of things led archaeologists to make the first classifications, which were based primarily on utilitarian criteria. In this way, it was possible to differentiate between those objects with some functional meaning (an arrow, a pot, a plough, etc.) from those whose meaning was less obvious or could not be assigned a specific function, these were associated with the ambiguous sphere of the symbolic (a lithic statuette, a decorated rib, the ochre scattered on a buried body, etc.). Within this last group, rock art was – and still is – one of the cultural productions that has received most attention from researchers, precisely because of the difficulties involved in accessing its meanings. Even in ethnographic cases, where there was the possibility of working with aboriginal communities that continued to produce rock art beyond the middle of the twentieth century (Sanz et al. 2017), the problem of meaning continued to persist,

mainly, because the different representations were liable to different readings according to gender, age, or social position of the community member who officiated as an informant in that occasion.

The meaning of rock art, and the meaning of archaeological objects in general, was always slippery, or inaccessible. However, archaeology, throughout its history, sometimes with greater and sometimes with less intensity, sought to develop theoretical and methodological tools that facilitate some approximation to meanings. Many times these tools were borrowed from other disciplines. From the 1960s, archaeologists found in semiotics a theoretical framework that provided various methodological and analytical resources that enabled systematic approaches to problems not even considered by traditional archaeology. Rock art studies were, possibly, the ones that benefited most from the encounter between semiotics and archaeology, fostering the development of special interest areas: analysis of the structure of rock art designs, syntax of images and use of support, typology of representations and stylistic correlation, social aesthetics, cognitive studies of image-interpreter relationship, and analysis of interpretive habits in the context of the use of images, among other topics. In this opportunity, we will focus on the contributions of semiotics to the study of meanings in rock art, perhaps, the most controversial and interesting of the contributions.

Definition

The two main definitions of semiotics correspond to its founders: the Swiss linguist Ferdinand de Saussure (1857–1913) and the American philosopher Charles S. Peirce (1839–1914). The name that Saussure gives to this discipline is that of semiology and defines it as the science that studies the life of the signs within society. In addition, Peirce, uses the term semiotics and defines it as the formal doctrine of the signs that seeks to discern the necessary conditions of the object it studies. Although both conceive the sign as the object of primary study, its theoretical conception will be different and that difference will determine the ways in which its study is approached and the interpretations that are made (Preucel 2006).

For the Saussurean perspective, with linguistic bases, the sign is everything that tells us about something other than itself and is conceived as a purely mental entity independent of the material world, consisting of a signifier and a signified. The relationship between the two is a social convention established by the user community. Besides, Peircean semiotics, with philosophical logic bases, defines the sign as something that is in something else's place under some aspect or capacity and conceives it as an entity made up of three elements: object, representamen, and interpretant. In this triadic conception, the material world (the object) is part of the sign and can condition, to a greater or lesser degree, its mental representation (representamen). Such representation will later be associated with a meaning (interpretant) that can be a concept, a new sign, or an action. In this way, Peirce provides a pragmatic view of the sign, not considered by Saussure, in which he argues that the interpretation of a sign will generate certain practical consequences, which will complete its meaning. That is, the meaning of a sign will have different characteristics and effects depending on the relationship it establishes with each of its constituent elements, giving rise to different sign classifications.

For archaeology, the classification that proved most useful is the one that considers the sign-object relationship and allows differentiating between icon, index, and symbol. In the first, the relationship of significance is given by the similarity between the sign and its object of reference, be it real or imaginary. In the index, which defines a mode of significance that indicates the contextual existence of an entity, the relationship is established by contiguity, causality, or factoriality. Finally, in the symbol, the relationship between sign and object is a social convention. It is important to note that, what for Peirce is only one type of sign, the symbol, corresponds to the more general conception of Saussure's sign.

Knowing these elementary theoretical differences between the two main semiotic traditions will allow us to better understand the different semiotic approaches applied to rock art, which

are basically divided into (a) structuralist approaches that apply concepts and methodologies derived from structural linguistics, showing particular interest in the role of representations in social communication processes (e.g., Troncoso 2008) and (b) pragmatic approaches that put emphasis on aspects related to the agency of rock art and associated social practices that generate meaning (e.g., Ambrosino 2017).

On the other hand, rock art can be defined in broad terms as any visual art representation made on a rocky support through different engraving and/or painting techniques. Like any human production, rock art is the result of a creative process, an artifact, but with the particularity of being the graphic representation of something, where that something can have – or not – a real material existence. As a creative process, mediated by thought, rock art carries a communicative purpose (Troncoso 2007; Vogt 2014, among others). Such characteristics give rock art the necessary conditions to be considered a sign and, consequently, subject of study of semiotics.

Historical Background

In Robert Preucel's book, *Archaeological Semiotics* (2006), he emphasizes that the relationship between archaeology and semiotics is mostly expressed through the use of some of its methodological tools in research with diverse theoretical orientations and not in the explanation of specifically semiotic theoretical frameworks. Although in recent years a significant number of papers have been published that propose semiotics as the main theoretical-methodological resource for the analysis and interpretation of their data, Preucel (op cit) recognizes that it is in structuralism where we will find the farthest information of semiotics' contributions to archaeology.

The impact of structural linguistics of Saussurean roots in the social sciences gave rise to what became known as the "linguistic turn," which had its greatest expression in the 1960s. It is in this context that Claude Levi-Strauss, strongly influenced by linguist Roman Jakobson, lays the foundations of *Structural Anthropology*. Like that famous phrase from Antoine de Saint-Exupéry's *The Little Prince* (1943) "the essential is invisible to the eyes," *Structural Anthropology* focused on the deep structures of cultures (supposedly universal mental structures), which were those responsible for the way in which the material and social aspects of these cultures were presented to us. This key principle of structuralism has its origin in the dual structure of the sign: the signifier, what we perceive, and the signified, the associated concept. Therefore, the study of objects (signs) of extinct cultures put archaeologists in the face of the particular situation of having the signifiers but no longer their signified.

In this scenario, the linguistic model provided a solution to the problem. On the one hand, the generative rules of the language and its linear principles offered certain similarities with the manufacturing process of the artifacts (Preucel 2006). On the other, the Saussurean concepts of significance and value of the sign allowed us to recognize that the meaning of the sign depended not only on its intrinsic meaning but also on the relationship of similarity, difference, and opposition with other signs and, consequently, on the articulation – syntax – among them.

André Leroi-Gourhan (1968) and Anette Laming-Emperaire (1962) were the first to apply the theoretical concepts of structural linguistics and Saussurean semiology for the analysis of Paleolithic rock art. To do this, they used a system of binary oppositions that allowed them to identify the organizational principles of the rock art assemblages, which would reveal the significant underlying structure. As Moragón Martínez (2007, 17) says, "the Structuralist tradition offers a vision of culture as a text; governed by hidden laws and rules that must be decoded in order to understand the meaning of what is presented in the registry."

Basically, for Leroi-Gourhan, Paleolithic art was ordered according to the feminine-masculine opposition where, given certain formal analogies between the human anatomy and that of some animals, the feminine was represented by the figure of the bison and the masculine by that of the horse. Then, from the analysis of the distribution of these representations in the caves studied and

their relationship with other representations that alluded to different animals or abstract motifs, Leroi-Gourhan proposes that the sets would configure narrative scenes associated with the fertility issue. Yet, Laming-Emperaire, disagreed to some extent with such interpretations. For her, contrary to what Leroi-Gourhan proposed, the feminine was associated with the figure of the horse and the masculine with the bison, and the alternation of such images would have represented a society organized in halves.

The criticisms that followed these proposals greatly discouraged the application of semiotic frameworks to the study of rock art. The questions mainly pointed to their psychological interpretations, the lack of chronological control in relation to the production of representations, their scarce interest in broader theoretical approaches (Preucel 2006), and the use of a style concept that was not systematic and operational enough to be applied to rock art and that it did not account for its active role (Troncoso 2007). However, although less frequently but with new approaches within the Saussurean perspective, semiotics continued to be a theoretical-methodological option for rock art studies. In the decades after the 1960s, interest in the meaning of rock art dropped down to give rise to the question of how rock art signifies, deepening the syntactic and contextual aspects, the perceptual analyses of rock art productions, and their impact in the structuring of the communication systems of past societies (Sauvet 1988; Kechagia 1995, among others).

It is worth noticing that we have not included in the historical background, examples of studies of rock art that have been carried out applying Peircean semiotics. However, such a peculiarity would have its explanation in the late resurgence of Charles Peirce's work in the field of social sciences and humanities. As for archaeology, the consolidation of postprocessual currents in the 1980s and 1990s favored the consolidation of material culture studies, which provided a pragmatic view, understanding it as an active social practice constitutive of the social order. This new perspective fostered an approximation of archaeology to Peircean semiotics, which begins to be considered methodologically more systematized at the beginning of this century (Preucel and Bauer 2001). As we will see next, the application of Peircean concepts to rock art studies is relatively recent, and they have come to provide proposals that exceed the question of the representations' significance to explore the practical consequences of rock art production in the network of significant relationships that account for issues such as the construction of social landscapes, memory, identity, and power.

Key Issues/Current Discussions

At present, it can be seen that the debates about the semiotic study of rock art preserve the Saussurean/Peircean dichotomous perspective. The investigations of the first group maintain, in a broad sense, the theoretical conception that rock art is a visual communication system and, as a communication system, will share similar structures with the language system and the existence of a code that allows its recognition and interpretation.

Along these lines, Paul Bouissac is one of the researchers who has investigated the most in the development of a semiotic methodology to address the problems of significance in Paleolithic rock art. His proposals regarding the existence of a possible early writing system are based on rigorous and exhaustive statistical analyses that allow us to define, not by perceptual assumptions, whether the spatial, technical, and stylistic relations between the representations that make up the rock art assemblages respond – or not – to particular combinatorial rules. According to the author, confidence in the method is growing given that the continuous advances in the knowledge about the cognitive capabilities of Paleolithic humans are reversing the old ideas that denied these populations complete linguistic and symbolic competence. Therefore, as long as the archaeology of this period continues to reveal other types of graphic productions that are recognizable as symbolic, they can be compared with the rock art sets through statistical correlation tests that allow identifying the recurrence of particular combinatorial patterns, which would increase the

chances of recognizing textual properties in some of these rock art sets (Bouissac 2006, 2009).

From a similar perspective, Andrés Troncoso (2007) proposed style as a specific semiotics for rock art. He defines style as a broad standardized system that responds to the encyclopedic code that a society possesses at a given time and space. The production of rock art and the rules that stipulate how its elements can be combined are given by the code, so the analysis of the rock syntax is shown as a possible access path for the decoding of the system. The author maintains that style is the individual materialization of a supra-individual reality that gives the intelligibility framework. In the same way, such supra-individual reality will also affect the styles of other material productions, both visual and objectual, offering opportunities for comparing the syntax of the elements that compose them and thus have other ways of accessing the code of the same intelligibility horizon. The use of the space in the rock art panel and the criteria for selecting the site with rock art are also part of Troncoso's concept of style: first, because it defines the way in which the composition is ordered inside the panel from a specific syntax between the elements of the rock art assemblages, which allows to identify the basic principles of the code of the semiotic system, and second, because the spatial location of the site accounts for the domain of validity of the semiotic system and orders the social space (Troncoso 2007, 2008).

Finally, we could say that the studies of rock art that apply Peircean semiotics tools do not attempt to elucidate the meanings of the representations but to understand the practical consequences of rock art production in the rest of the a community spheres of action.

For example, Vogt (2014) proposes a more pragmatic view that takes the focus out of the rock art representation in itself to investigate more systematically the relationship between rock art and landscape. Based on the study of numerous sites with rock art from the south of the Scandinavian region, the author carries out a socio-semiotic analysis of the spatial distribution of rock art and its relation to available resources and roads. He maintains that rock art production was a means to impregnate a landscape that intended to make explicit certain messages about power and identity. While recognizing that the main role of rock art as a semiotic system is its ability to communicate, he postulates that it necessarily acts in relation to other semiotic systems with communicative logics other than linguistics. Rock art is a visual strategy that cognitively models space, influencing its perception and allowing greater political and ideological control than can be achieved through physical power.

Another interesting line of research is proposed by Cabak Rédei et al. (2018), who apply the concept of cartosemiotics for the analysis of a rock art set in Aspeberget, Sweden. The proposal considers the analysis of the representations following the Peircean classifications and paying particular attention to the way in which certain figures are combined with others giving rise to specific themes. For its part, the cartosemiotic perspective assumes that the rock art set can be understood as a kind of map – not in the current sense of the map – which provides a representation of the world where social practices, spatio-temporal conceptions, and a variety of signs that allude to the main referents of the material culture and subjects – or the social roles of such subjects – of that community or neighboring communities at a given moment in their history are interrelated. The semiotic reading of the coordinates of these maps will allow to differentiate the local and the foreign, as well as the peaceful or conflicting intersocial relations. The authors conclude that the analyzed panel represents what is important for the society that produced it and, as a map, schematizes a model of spatial relationships that would have been necessary to know in circumstances such as long-distance travel.

Another example to consider is the work of Ambrosino (2017), who from the tripartite semiotic model icon-index-symbol tries to understand the way in which rock art participates in the social construction of the landscape in a sector of the central Andes and, in turn, interpret its agency in the configuration of intersocietal relationships over a temporal segment of approximately 3,000

years. The author argues that rock art, in the period studied, acted as a semiotic means of reference to the past, constituting a mnemonic device that linked specific identities to specific places and at different scales. The originality of his proposal lies in a dynamic vision of rock art, oriented to its agency in social processes, that is, oriented to the understanding of its role as a connector of different planes of social significance: identity, memory, power, space, mythical time, etc.

International Perspectives

We still observe, on a global level, that the semiotic approaches to the study of rock art and their meanings remain within the limits of the two main spaces of semiotic thought, originally proposed by Saussure and Peirce. Although it is difficult to find studies that seek to assemble both methodologies, it is less difficult to identify certain common trends, such as the incorporation of the spatial analysis of rock art sites' locations and their relationship with the configuration of past landscapes.

However, depending on the theoretical-methodological perspective that is applied, the analysis of the space will grant different interpretative possibilities in relation to rock art and its meanings. Lindström et al. (2014) argue that, in the semiological/structuralist (Saussurean) approach, the landscape is conceived as a system of signs where its various elements are assumed as a coherent whole; in this way, each phenomenon, each trait, will be related to another according to certain codes. Thus, the rock art site, as a sign, is susceptible to being analyzed syntactically in relation to a spatiality greater than that of the site itself, revealing structural relationships with the other elements of the landscape and configuring for its inhabitants a communicative system in itself.

From the Peircean approaches, the landscape assumes a more dynamic role in its interrelation with rock art. These approaches, tacitly based on the Peircean concept of *synechism* – a tendency to consider the whole as a continuum – offer an appropriate theoretical model to understand the practical consequences of the sign interactions. For example, considering Hodder's concept of entanglement (2012) – which I assume as a true semiotic model for the analysis of the pragmatic dimension of object-subject dynamics – the significant relationship between rock art and landscape could arise from the following form: rock art modifies space, modified space influences the perception of subjects, such perceptions derive in specific behaviors and practices, these practices have material consequences on space, which is again modified and re-signified, and so *ad infinitum*.

In short, the general trend in rock art studies and meaning is to look for broad contextual perspectives that allow consideration and analysis of all other semiotic systems that influence, affect or condition the production, function, use, agency, form, and content of rock art.

Future Directions

In a relatively recent work, Kull and Velmezova (2014) collect the opinion of more than 30 semiologists regarding the new challenges that semiotics must face as a discipline. In their conclusions, the authors identify a series of disciplinary needs that should be addressed in the near future, of these, I would like to highlight the following: (a) redefine its goals, its language and methodology, while reconsidering its past to provide an appropriate auto-description, (b) rethink its relationships with other disciplines, (c) respond in an appropriate manner to the demands of the contemporary world, especially favoring the production of new knowledge and theoretical tools.

This synthetic semblance of semiotics' current problems is important to understand the future perspectives of semiotic studies on rock art and meaning. In relation to the first of the mentioned needs, its impact is direct. Until the main semiotic currents are terminologically and methodologically reconciled, the application of semiotics in the study of rock art will continue to be through particular methodological tools and not as a

concrete theoretical framework, with the consequent indeterminacy on the possibility of accessing the meanings: can we really access them or should we just settle for approximations to their possible ways of signifying? The second need raises a more affordable objective: interdisciplinarity. The success of semiotic studies on rock art and meaning lies entirely in interdisciplinary approaches. Which, automatically, leads to a partial response to the third need mentioned, since the interpretive requirements of rock art would lead to the development of specific semiotic methods for the understanding of temporarily distant material realities.

Until these contingencies are resolved, deepening the semiotic aspects of rock art as an object poses a promising future for these studies. Today, the indissoluble unity and co-dependence between mind and matter is evident, which allow us to affirm that the mind is embodied and extended to the material world: human beings know, do, and install themselves in the world in open systems that include embodied brains, social networks, or resources and key parts of the natural and cultural world and that are true social, political, economic, ideological, and cultural networks. Seen on this light, the link between the world and the subjects are the objects; both constitute the symmetric nodes of those networks in which the agency, understood as the ability to act onto another, lies in the relationships between them.

Peircean semiotics is closely related to the Theory of Material Engagement (Renfrew 2004) because the former understands that the sign is distinguished by the contours of its significant effect and semiosis as a relative and relational property, independent of language and behavior, and linked to particular experiential situations. Everything that exists (and rock art exists!) is likely to be read as a sign, all signs display an agency of diverse kinds and, consequently, agency and meaning are comparable (Giraudo and Martel 2015). From this perspective, an affirmative answer to the question asked above about whether or not we can access meanings is increasingly likely.

Rohr, João Alfredo

Tiago Attorre
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Basic Biographical Information

João Alfredo Rohr was born in 1908 at Arroio do Meio, Rio Grande do Sul, in southern Brazil, amidst a community of German Catholic immigrants. At the age of 12, at a time where there were no universities in the southern part of the country, he left to attend a seminary maintained by the Society of Jesus. It was in Pareci Novo, and later, São Leopoldo, that João Alfredo pursued his education for the next 20 years, until finally becoming an ordained priest of the Jesuit Order (Schmitz 2009).

Father Rohr's first assignment was to teach at the traditional school that the Jesuits had established in 1905 at the city of Florianopolis. Father Rohr taught chemistry, physics, and natural sciences at the Catarinense School for 22 years. As a Jesuit, he had a strong background in Humanities and Natural History (Schmitz 2009). The school had a small museum, which Father Rohr expanded into the Museum of the American Man and later into the Museum of the Sambaqui Man (shell mound builders). In 1956 the Anchieta School was founded in Porto Alegre, RS, and with it the Anchietan Research Institute, which gathered together many Jesuit researchers working in South Brazil. The institute disseminated the work done by its associates and preserved and promoted previous achievements.

Major Accomplishments

It was within the field of archaeology that Fr. Rohr became well known. His first achievement was to secure the Carlos Behrenheuser

Collection, comprised of more than 8,000 artifacts related to the *sambaqui* (shell mound) builders that abound in the south coast of Brazil and 80,000 artifacts and fragments of pottery related to the Guarani groups. After that, in 1958, Fr. Rohr started his surveying and excavating efforts to locate and identify archaeological sites in the region. This task extended for 24 years, until 1982. At the same time, Paulo Duarte, of the University of São Paulo, and José Loureiro Fernandes, of the Federal University of Parana, were gathering archaeologists from abroad in order to improve scientifically oriented archaeological research in Brazil. Fr. Rohr accompanied the French researcher Annette Laming-Emperaire in some excavations in Paranagua and Lagoa Santa and attended the first seminar held in Brazil by the American couple Clifford Evans and Betty J. Meggers, regarding the research of pottery archaeological sites (Schmitz 2009).

Fr. Rohr recorded more than 400 archaeological sites and excavated many of them. The archaeology that he practiced encompassed all elements present in the State of Santa Catarina's archaeological record. Although the answers to the questions present in those elements could not be addressed exclusively within the state's borders, Father Rohr's approach helped to expand enormously the knowledge about the diversity of the southern Brazilian archaeological record as a whole.

In 1972, along with Brazilian authorities, Fr. Rohr initiated a huge effort to protect the archaeological record from being destroyed, especially the big shell mounds, which were being explored for commercial purposes. Thanks to these efforts, many of those mounds, built through several millennia, are still standing along the southern shores, allowing archaeological investigation of an enduring coastal culture (Reis and Fossari 1984).

Father João Alfredo Rohr stands as a true pioneer of Brazilian archaeology. He lived in a time of transition and managed to educate himself and the public in order to establish archaeology as a field of research and secure the way for many other future researchers.

Roman Army, Archaeology of

Michael J. Taylor
State University of New York at Albany, Albany, NY, USA

Introduction

The Roman army was perhaps one of the most influential and enduring human institutions of the ancient Mediterranean world: its history spans over a millennium, from its origins as a community muster to an imperial force deployed across Europe, Asia, and North Africa. The army was the sine qua non of Rome's empire, and it generated enormous cultural, social, religious, and economic interactions within this imperial configuration. Archaeology provides critical insights to how the Roman army operated both as a combat force and as a community. Archaeological research has the capacity to (1) supplement, clarify, and at times correct information provided by textual sources, (2) recover physical specimens of Roman arms and armor, (3) provide visual

representations of soldiers' clothing and equipment, (4) reveal the daily life of Roman soldiers in garrison, (5) excavate fortifications and camps, (6) identify the location of battles and sieges, and (7) recover new texts, such as inscriptions, papyri, ostraca, diplomas, and wooden tablets. Archaeological discoveries represent the only new source of information about the Roman army, supplementing a staid canon of classical texts and offering dynamic new perspectives on the subject.

Definition

The Roman army represented the organized military force of the Roman state in its various permutations, from an archaic city-state, to a Republican conquest state, to an imperial monarchy overseeing a stable pan-Mediterranean empire that endured into the fifth century CE. The Roman army experienced substantial developments over this period, transforming from a civic militia into a professional force. The army outlasted the Western Empire, as some military units in the West continued as corporate entities after the overthrow of the last emperor in 476 CE. In the East, the *Legio V Macedonica*, formed by Octavian in the 40s BCE, persisted, albeit in a much evolved formed, until the Arab conquests of the seventh century CE.

Historical Background

Little archaeological evidence about the Roman army comes from Rome itself during the earliest periods of Roman history. Rather, we must rely on Central Italian weaponry and equipment from tomb deposits, as well as visual representations of Italic warriors such as wall paintings, vase painting, and votive figurines. The evidence collectively suggests that Greek-style hoplite equipment was widespread across Italy, with heavily armored infantrymen fighting behind large round shields. Indeed, the earliest depiction of hoplite warfare anywhere in the Mediterranean comes from the so-called Chigi vase, made in Corinth in the seventh century BCE but unearthed in an Etruscan tomb, featuring two formations of hoplites advancing in close order. It is unclear that the use of hoplite weapons in Italy coincided with the adoption of such close-order phalanx tactics, although a fourth century BCE wall painting from Lucania also depicts two dense formations of soldiers with locked round shields facing off against one another.

One piece of epigraphic evidence points to the existence of private warfare in the Early Republic, coexisting along with the state musters of Central Italian communities. A sixth century BCE statue base from the site of Satricum in Latium reads "the companions (*suodales*) of Poplios Valesios set this up for Mars" and is commonly interpreted to represent a dedication by a band of armed retainers, perhaps loyal to the Publius Valerius Publicola who features prominently in the narrative tradition of the Early Republic (*Année épigraphique* 1982 161). Nonetheless, by the fourth century BCE, these war bands were largely subsumed by the growing power of community armies (Armstrong 2016).

The rise of Roman hegemonic power in the fourth century BCE may have prompted cultural changes across Italy that limit our ability to reconstruct subsequent Italian military equipment. With Roman hegemony, elite burial practices changed, with less emphasis placed on burial with weapons or martial iconography in tomb painting. Given that iron weapons degrade unless preserved in anaerobic conditions such as tombs, we have fewer examples of weapons from the Middle and Late Republic than we do from Archaic Italy.

The panoply that emerged by the Middle Republic was largely derived from the Celts and can be reconstructed from visual evidence, especially the Pydna monument of Aemilius Paullus at Delphi (c. 168 BCE) and the so-called Altar of Domitius Ahenobarbus (c. 100 BCE), portions of which are now in the Louvre (Stilp 2001 (Ahenobarbus); Taylor 2016 (Pydna battle scene). For defense, a Roman infantryman carried a large curved oval shield, the *scutum*, an Italic variation on the Celtic *thureos* ("door") shield. The *scutum* was featured on a bronze currency bar issued in the early third century BCE, on the

poorly preserved tomb painting today known as the Esquiline Historical Fragment (c. 325–250 BCE), and the Pydna and Ahenobarbus monuments. Only a single Republican-era *scutum* has survived, preserved in the dry conditions of the Fayum in Egypt. The Fayum *scutum* is not Roman, but probably a copy of a Roman-style shield used by Ptolemaic forces, who had widely adopted Roman equipment by the first century BCE (for military equipment throughout the Roman period, see Bishop and Coulston 2006).

The most common helmet type in Republican Italy was the Montefortino, characterized by a distinctive crest knob and a high conical dome, initially developed in the Celtic regions of Northern Italy. It was eventually widely used across Italy and beyond, although by the First Punic War, it had become closely associated with Rome (Burns 2003). Plumed Montefortino helmets decorated Roman naval rams from ships sunk in 241 BCE, although some of the Montefortino helmets recovered from the seafloor after that Roman victory were likely worn by Gallic or Italic mercenaries serving Carthage. Other helmet types persisted, including the Apulo-Corinthian and Phrygian-Attic types, attested in both the iconographic and material records.

Celtic mail armor (*lorica hamata* or *lorica gallica*), constructed from small, interlocking rings of iron or copper alloy, was by the second century BCE mandatory equipment for wealthy infantrymen. Mail armor protects the soldiers on the Pydna and Ahenobarbus monuments, and a few mail fragments were unearthed at Numantia. Polybius (6.23.14) reports that poorer men wore chest protectors a span wide, probably referring to a small round breastplate, an example of which was excavated at Numantia (Spain). A number of Italian bronze figurines from the Middle Republican period feature infantrymen without any body armor to supplement their helmet and shield. Some Etruscan and South Italian figurines still featured muscle cuirasses, which are also worn by some of the soldiers on the Pydna monument, perhaps an attempt to differentiate Italic allies (*socii*) from legionaries in mail.

A mix of Greek- and Celtic-style swords were used by Roman and Italian soldiers into the Second Punic War. A Greek-style stabbing sword (*xiphos*), similar to blades preserved in South Italian tombs, was used to decorate an early third century BCE stamped bronze currency bar. And a late fourth century BCE Celtic-style sword found in San Vittore del Lazio was proudly stamped "made in Rome" (*fecet Roma*). During the Second Punic War, Roman soldiers in Spain adopted a Celtiberian blade that became the famous *gladius hispaniensis*, or Spanish sword, which has been identified archaeologically by comparing blades found in likely Roman military contexts to Celtiberian swords preserved in tombs (Quesada-Sanz 1997). The *hispaniensis* had a c. 60–70 cm blade, sometimes slightly waisted, with a long point, suitable for both stabbing and slashing as described by Polybius (6.23.7). Prior to engaging with the sword, Roman soldiers threw javelins (*pila*), which consisted of iron shanks, attached to a wooden shaft. Nineteenth-century experiments with reconstructed weapons overseen by Napoleon III's Chief of Artillery suggested a maximum range of 30 meters.

Only a few battlefields from the Republican period have been identified archaeologically, in part because the Romans did not build monumental memorials, in contrast to Greek practice, e.g., the Theban shield monument at Leuctra. On the naval side, the recent discovery of naval rams, ballast, storage amphora, and helmets on the seafloor off of the Egadi Islands has starkly illuminated the last great naval confrontation of the First Punic War, fought in 241 BCE. The archaeological evidence has offered a sobering check on the literary sources, as the recovered rams suggest that Roman warships were much smaller than the massive *quinqueremes* that Polybius (1.29.9) reports in his account of the war (Tusa and Royal 2012). A team of Spanish archaeologists has recently identified a major Second Punic War battlefield in the upper Guadalquivir valley, most likely from the Battle of Baecula in 207 BCE (Bellón et al. 2016).

Sieges are more conducive to archaeological recovery than set-piece battles. While weapons and equipment might clatter to the ground in a

battle, these generally landed in the open, easily recoverable after the battle, where stripping the dead was an organized task undertaken by the victorious side. Sieges, however, involved entrenchments where artifacts might be accidentally buried, along with the construction of enduring structures such as earthworks, semipermanent camps, and ramps. From the Republican period, the most impressive set of excavated Roman camps were those used to besiege Numantia in Spain between 153 and 133 BCE. Excavations overseen by Adolf Schulten in the early twentieth century provide the most important archaeological record of the Republican army in action, suggesting that Roman camps hewed roughly to the theoretical model of a Roman camp described by Polybius (6.27–31), although the plan was flexibly adapted based on the terrain and the varying size of the unit housed within (Dobson 2008).

The Roman army evolved significantly between the Middle and Roman Republic, a process often incorrectly dubbed the "Marian reforms." The archaeological evidence for the Marian reforms is tenuous. The quality of Montefortino helmets declines somewhat in the late second century BCE, but this cannot be conclusively linked to Marius' drafting of impoverished *proletarii* into the army. The report by Plutarch (*Marius* 25) that Marius retooled the *pilum* with a wooden rivet to cause it to break off in enemy shields is patently disproved by subsequent *pila* with two metal rivets.

Intensive warfare defined the Late Republic, both in terms of expansion (Pompeius Magnus in the East, Julius Caesar in Gaul) and increasingly savage civil wars. Pockmarks on the walls of Pompeii, along with recovered catapult balls, testify to Sulla's siege of the town during the Social War (91–88 BCE). The excavations of Valencia in Spain illuminate a horrifying moment in the extended civil conflict, when Pompeius sacked the city in 73 BCE, having captured it from forces loyal to the warlord Sertorius. Excavators discovered the skeleton of an elderly man with his arms bound behind his back, sodomized to death with a *pilum*. A young man of military age was found with all of his limbs hacked off (Alapont 2009). The skeletal evidence seemingly confirms Polybius' earlier report (10.15.5) that mutilation of human corpses while sacking towns was standard practice as a terror tactic, although the circumstances of civil war might bring out special brutality. The civil wars that destroyed the Republic give us some of the first funerary monuments for Roman centurions, most notably that of Minucius Lorarius ("the flogger"), who died near Padua in 40 BCE. His full-body image represents perhaps the earliest visual representations of a centurion's iconic grapevine stick (*vitis*).

Military reforms effected by Augustus radically increased the archaeological visibility of the Roman army. Augustus transformed the citizen militia of the Republic into a truly professional force. Roman legions became standing units, permanent communities, as well as combat formations. The histories of individual legions can be traced archaeologically, even as they redeployed around the empire, through brick stamps marking the product of legionary kilns. The increasing mobility of many soldiers, combined with their growing sense of corporate identity, contributed to the explosion of the epigraphic habit near military bases. Tombstones frequently present images of soldiers, a treasure trove of information concerning military equipment, clothing, career patterns, and martial self-representation more broadly.

While Augustus initially carried out active conquests on the Rhine and Danube, expansion largely ceased late in his reign, and legionary camps soon developed into permanent bases. The site of Inchtuthil in Scotland, abandoned in the Flavian period and never built over, provides a particularly pristine view of a Roman legionary camp, including a hoard of nearly 10 tons of nails (Shirley 2000). The bogs at Vindolanda have preserved a sizable collection of wooden and leather goods, as well as textile fragments. Other camps, occupied for centuries, accumulated buildings, inscriptions, trash middens, and sundry deposits that offer rich insight into the daily life of the Roman army.

Conditions at some permanent bases proved conducive to preserving written texts. Records written on ostraca survive from the legionary camp at Bu Njem in Libya and the military district surrounding the mines of Mons Claudianus in

Egypt. At Vindolanda in Britain, wooden tablets written upon with ink illuminate the daily life of the Roman army: a birthday invitation, in Latin, from one army wife to another; a shopping list of comestibles for the camp Saturnalia festival, including Mediterranean fish sauce and Celtic beer; and a complaint to the cohort commander from a merchant claiming he has been beaten, presumably by soldiers. Other original records, including papyrus from Egypt and Dura-Europos, as well as tablets from Vindonissa, provide a sample of the vast quantities of official paperwork army units processed, such as daily strength reports, to casualty reports, pay stubs, furlough requests, letters of recommendation, and so on (Fink 1971).

The Augustan period also brought rapid changes in military equipment. A new type of body armor, dubbed *lorica segmentata* by modern archaeologists, consisting of a complex series of interlocking metal strips was in use by 9 CE. The Montefortino, along with the closely related Coolus helmet, gave way over the first century CE to the Imperial helmet, subdivided into Gallic and Italic varieties based on early findspots. The primary advantage of the new helmet was an enormous neck guard, not dissimilar that of a modern-day firefighter's helmet, which offered protection in sieges as well as for legionaries in a combat crouch. The legionary *scutum* underwent some modifications, mostly detectable in the visual record, becoming shorter and more rectangular. The so-called Mainz style gladius, along with the closely related Fulham type, was essentially a shorter and stouter version of the old *hispaniensis*. The Pompeii type, which emerged in the later first century CE (named after blades preserved in the Vesuvian eruption of 79 CE), featured a short blade with parallel edges and a short triangular point. In the second century CE, a type of ring-pommeled sword entered service, probably borrowed from the Sarmatians on the lower Danube.

Perhaps the most famous battle of the Imperial period, the defeat at the Teutoburger Wald, is known primarily because of the efforts of Tony Clunn, a British military officer who located the battlefield at Kalkriese in Germany through years of metal detecting. Subsequent professionally managed excavations have provided new insights into the massacre of Publius Quinctilius Varus and his legions in 9 CE, including the care with which the Germans prepared the ambush site through earthworks, while also providing a cache of early imperial equipment, including the earliest dated piece of *lorica segmentata* and the earliest known cavalry face mask (Rost and Wilbers-Rost 2010). A recently discovered Roman military camp in eastern Germany near Thuringia, dating to the second century CE, and a battle site from the third century CE suggest that large Roman armies continued to operate far east of the Rhine, probably conducting large-scale punitive raids.

As with the Republic, sieges during the Imperial period provide the most concentrated archaeological record of combat operations. The sites of sieges are more likely to attract professional archaeologists, often interested in excavating the ancient community more broadly, rather than just uncovering a particular moment of armed combat. Ongoing excavations at Jerusalem have revealed many artillery projectiles fired as Titus' forces breeched the city's defenses in 70 CE, as well as cooking vessels and lamps left behind by refugees hiding in the sewer system. Perhaps the most famous remains of Roman siege works come from Masada, where Romans built an enormous ramp to capture the mountain fortress in 73 CE, the physical remains of which are still visible. While the Romans had used various types of catapults and other siege engines since the Middle Republic, the Imperial period provides more complete archaeological coverage of the technology (springs, washers, bolts, etc.). Evidence of the lethality of Roman catapults can be found in the skeletons of men killed by the Romans near Maiden Castle in Britain, where one Briton was transfixed by a bolt which lodged in his spine and another had his face collapsed, likely by a similar projectile.

The most stunning visual representation of the Roman army in action is Trajan's column, which features a spiraling series of intricate reliefs illustrating Trajan's two campaigns in Dacia (101–2/105–6 CE). While many aspects of the illustrated scenes find confirmation in the archaeological record, the artists took some liberties, not

dissimilar to the inaccuracies that crop up in modern war films. The soldiers on Trajan's column, for example, mostly wear a style of Attic helmet which was occasionally used for parade purposes (featured in representations of the Praetorian Guard) but seldom turns up along the frontier. Taking Trajan as a model, Marcus Aurelius (or his son Commodus) erected a similar monument commemorating the Marcomannic Wars (166–180 CE). On these columns, provincial auxiliaries are separated from citizen legionaries through their mail armor and flat oval shields, compared to legionaries in *lorica segmentata* and curved rectangular shields. Some differences in equipment did separate auxiliaries from legionaries, although perhaps not as starkly as the columns would suggest, for example, a flat oval shield from Doncaster appears to have been an auxiliary model.

These representations provide a blunt portrayal of Roman violence. Trajan's column celebrates headhunting Roman auxiliaries and features severed heads on poles in front of Roman fortifications. This visual scene has a physical counterpoint, as excavators at Vindolanda discovered disembodied skull just outside of the fort's wall, where it probably was at one point on display. Marcus Aurelius' column shows even more savage violence: a woman stabbed to death by a legionary, a village razed, and mass executions of German prisoners. A mass grave of decapitated bodies unearthed not far from Maiden Castle in Britain may represent forensic evidence of such a massacre. Another Trajanic monument, the *Tropaeum* at Adamklissi, shows Roman soldiers killing Dacian warriors with panache and savagely attacking a Dacian family riding in a wagon.

Starting in the reign of Claudius (d. 54 CE), provincial auxiliaries were granted bronze diplomas upon discharge from service, documentation of Roman citizenship granted to both them and their families as a reward for service. These diplomas document perhaps the most salient mechanism of spreading Roman citizenship in the provinces and provide insight into the family arrangements of auxiliary soldiers, as well as information about auxiliary recruitment and deployment.

Meanwhile, Roman soldiers in the provinces not only became exposed to foreign religious beliefs, but the social networks of army itself served as a means of disseminating religious ideas across the empire (Collar 2013). Roman soldiers erected altars and dedicated votive inscriptions to a wide array of gods outside of the traditional pantheon, including the Celtic horse goddess Epona, the Syrian Jupiter Dolichenus, the Germanic Matronae Aufaniae (or Matres), and Mithras, a deity worshipped in underground rites.

The Late Roman Empire saw a series of military crises, often lethal combinations of external invasions and destabilizing civil wars. The starkest illustration of the so-called Third Century Crisis (c. 235–284 CE) is illustrated by Naqsh-e Rustam, where a massive rock carving depicts the Roman emperor Valerian groveling in surrender before the Sassanid Great King Shapur I, also a rare vision of a Roman war from an opponent's point of view. The accompanying trilingual inscription proclaims, "Caesar lied and did wrong towards Armenia."

On the frontline between Rome and the Sasanian Persian empire, the fortified town of Dura-Europos, excavated between 1922 and 1937 (and sadly recently badly damaged by the so-called Islamic State), provides evidence of the garrison life of Late Roman soldiers in the east, including a religious calendar (*Feriale Duranum*) and a ceremonial shield. The frescoes of the synagogue, depicting Old Testament battle scenes, nonetheless featured the equipment of contemporary Roman soldiers. Dura also provides a grisly snapshot of siege warfare between the Romans and Sasanians prior to the Persian capture of the city in 257 CE. The Romans were in the process of sinking a countermine against the Sasanian mine, when the Persians, detecting their efforts, managed to cut a vertical shaft and asphyxiate the Roman sappers with toxic smoke, while the mine's collapse froze a moment of combat in time (James 2011).

Roman military equipment also experienced major changes in the Late Empire. Wide oval shields, sometimes virtually circular, became common, which could be more easily interlocked into a shield wall, the sort of close-order tactics described

in the literary sources and represented visually on the Arch of Galerius in Thessalonica and a fresco at Dura. The so-called ridge helmets predominated, made from separate sections riveted together, with the eponymous ridge connecting the pieces of the skullcap. The transition toward riveted helmets may be related to the rise of centralized mass production facilities (*fabricae*). Mail cowls displace helmets in some Dura frescoes, pointing toward common usage in the Middle Ages. Meanwhile, the relatively short *gladius* gave way to the *spatha*, a long sword of northern origin. The four tetrarchs can be seen clutching their long swords in the statue group from Venice, a reminder that the length of these swords may have been as much about display as tactical efficacy. A number of significantly cut down *spatha* (perhaps the *semispatha* referenced by Vegetius) have been found, either recycled into short swords following damage or perhaps intentionally shortened to make them more suitable for close combat. In place of the old *pilum*, Roman soldiers threw smaller darts weighted with lead, referred to in literary sources as *plumbatae* or *martiobarbuli*.

The major cavalry development in the Late Empire was the cataphract, a type of heavily armored cavalryman who anticipated the Medieval knight, borrowed from Iranian and Steppe riders. Sarmatian cataphracts are depicted on Trajan's column wearing head-to-toe scale armor, with their horses, similarly, if implausibly equipped with scales down to their hooves. A more accurate cataphract (probably Persian) is illustrated by a graffito at Dura-Europos, where a scale coat is draped over the horse's body. It is easy to see why such fighters were also known as *clibanarii*, or "boiler boys." A partial example of scale horse armor was recovered at Dura.

Meanwhile, military dress shows an enduring influence from the north. A collection of images of Late Roman soldiers is preserved on military tombstones from Apamea in Syria (Balty and van Rengen 1993). Many of these soldiers wear a long-sleeved tunic, a style imported from the north. Meanwhile, trousers, a quintessentially barbarian garment, had been worn in some form by Roman soldiers since the early second century CE, when they turn up on Trajan's column as short leggings worn under the traditional tunic. A military tribune at Dura offers a sacrifice while wearing dark trousers and a long-sleeved tunic. The consular diptych of the fifth century CE *magister militum* Stilicho also displays the long-sleeved tunic with trousers combination. In the mid-twentieth century, archaeologists identified a series of graves in Gaul as the remains of Germanic warriors in imperial service. The locations of these graves do not correspond well with the known stationing of *Laeti* units, and it is not impossible that some graves contained Romans who had adopted Germanic burial customs, or at least preferred to be buried with weapons (Halsall 1992). Regardless, the material culture of the Late Roman army reflected enormous Germanic influences, less a descent into barbarism than the recapitulation of a long-standing dynamic, dating back to the influence of the Celtic panoply on the Middle Republican army, in which military developments in northern Europe drove the evolution of Rome's fighting forces.

Key Issues/Current Debates

1) Women and Gender: Material evidence can shed light on the role of women in Roman military operations, even though they are largely excluded from ancient historical narratives. When Fulvia, the wife of Mark Antony, rebelled against Octavian at Perusia in 39 BCE, she personally commanded the forces under siege. Some sling bullets were inscribed with crass slogans, including two that proclaim that they are aimed at Fulvia's vagina (*FULVIAE LANDICAM PETO*). Ironically such bullets could only be read if they failed to hit their target (Hallett 2015).

   Material evidence also helps to reconstruct the role of women in garrisons. Women left behind a variety of gendered artifacts such as combs, brooches, and beads, suggesting that military camps were not gender-segregated zones, but contained numerous women as well (Allison 2013). Some were certainly prostitutes. A Flavian era tariff inscription from Koptos (OGIS 671) charges 108 drachmas for

a prostitute to pass into the military zone while charging ordinary women only 20. From the same military zone, an ostrakon documents the lease of a prostitute named Procla to a desert *praesidium* (O. Krok. 252). But others were wives of officers (common soldiers were forbidden to marry). The birthday invitation at Vindolanda (TVII 291), mostly written by an *amanuensis*, includes a brief personal note written in the hand of the army wife Claudia Severa to her friend Sulpicia, capturing the emotion and loneliness of women living on a far-flung frontier: "I await you sister" (*sperabo te soror*).

2) Literacy and Enculturation: The Roman army overall enjoyed unusually high rates of literacy, evidenced in part by texts produced by soldiers, ranging from inscriptions dedicated to fallen comrades to papyrus letters written home. Indirect evidence for literacy comes from seal boxes, which secured letters written on wooden tablets. The tablets and their contents have rotted away, but they indicate a letter was sent, assuming literacy for both a writer and reader. Unusual concentrations of these seal boxes in Batavia has been correlated to service in the Roman army, as Batavia was a prominent auxiliary recruiting ground, suggesting the seal boxes represent letters written home from soldiers serving abroad (Derks and Roymans 2002).
3) Animal Bones and Military Diet: Analysis of zooarchaeological remains from military sites suggests that Roman soldiers ate substantially more beef than their civilian counterparts back in Italy, who favored pork (King 1999). The beef-heavy diet of Roman soldiers (who still ate more pork than natives in Britain and Germany) may have reflected the dietary influence of locally recruited auxiliaries, the pastoral ecology of the frontier regions, as well as the effect of military demand for cowhide (for tents, shoes, saddles, etc.) on local husbandry patterns.
4) Grand Strategy: Since the publication of Edward N. Luttwak's *The Grand Strategy of the Roman Empire* (1976), scholars have debated the extent to which Rome practiced centralized strategy in its military deployments and dispositions. The remains of Roman fortification systems collectively embody the massive resources of the empire and have been used to reconstruct the possibilities and limitations of Roman grand strategy. Hadrian's Wall in northern England inevitably looms large in such debates, a project personally initiated by the emperor during a visit to Britain in 122 CE (Breeze and Dobson 2000). The top-down plan of the Wall, with milecastles every 5000 feet and guard towers every 1⁄3 of a mile, was rigid, so that milecastle gates occasionally opened onto cliffs and watchtowers were raised on heights that already offered commanding views. During the Wall's use, watchtowers were abandoned or demolished, and milecastle gates bricked up, decisions presumably made based on the facts on the ground rather than dictates from Rome. The actual strategic goal of Hadrian's Wall is much debated, although certainly the structure could simultaneously prove an argument in stone as well as a substantial barrier to mobility along the frontier. It is important to note the diversity of Roman fortification systems; the forts, walls, and outposts of heavily militarized frontiers such as Britain, Germany, and the Upper Euphrates might follow a very different logic than those in provinces that lacked a serious external threat, such as North Africa and Judaea (Wheeler 2007).

International Perspectives

Given the far-flung deployments of Roman military units, the study of the Roman army is spread across numerous national scholarly traditions. Spanish archaeologists focus on Republican sites associated with the conquest of Iberia, while the archaeological traditions in Britain, the Netherlands, and Germany have tended to focus on imperial frontier garrisons and fortifications sometimes literally in their backyards. In the 1960s, Israeli excavations related to the Jewish War were closely tied to the new national project: Yigael Yadin, who excavated at Masada and the Cave of Letters, a refuge likely used by survivors of the Bar Kochba revolt in 135 CE,

had previously served as the chief of staff of the Israel Defense Force.

Future Directions

Only a fraction of battlefields (or naval seascapes) attested in the literary sources have been confirmed archaeologically (e.g., Baecula, the Egadi Islands, and Harzhorn above); most are instead known from topographical speculation based on close readings of literary sources. Battlefields can be identified archaeologically from javelin heads, sling bullets, and even the hobnails from legionary boots (*caligae*). Archaeological exploration of battle sites has the potential to improve our understanding of specific military events and help develop a more thorough portrait of the Roman army in action. Of course, the future direction of material aspects of the Roman army will be largely determined by both the serendipity of discovery and creative reevaluation of current artifacts.

Roman Wall Painting

Eric M. Moormann
Institute for Historical, Literary and Cultural Studies, Radboud Universiteit, Nijmegen, The Netherlands

For many people interested in the ancient world, one of the most attractive aspects of Roman art is the wealth of wall paintings in houses of Pompeii

and other towns as well as villas buried by Vesuvius. Since their discovery in the eighteenth century, these and later found paintings have formed highly esteemed objects, for which reason they play a major role in art history. The study of Roman wall painting uses to start from this material and bases its chronology, which covers an era beginning in the second century BCE and ending with Vesuvius' eruption in 79 CE, on an articulation established by the German scholar August Mau in the 1870s during his in-depth explorations of Pompeii's ongoing excavations (Mau 1882; cf. Eristov and Monier 2014). Mau divided the bulk of Pompeian material he knew – which has grown ever since on account of additional findings but at the same time often no longer available due to bad conservation and loss of much data – into four chronological phases, which he called "Styles."

As a rule, Roman painting entails the rendition of architectural elements and precious materials into wall-covering architectural façades, compositions of panels, and articulations into horizontal and vertical zones filled in with parts of these elements. While we should never expect a more or less realistic *trompe l'oeil* of a really existing (or even plausible) architectural façade, although a painted decoration may look like those of lavishly adorned Roman theatre and fountain buildings, the painters created an entirely fantastic and illusionary world which in few cases looked like a realistically architectural composition. Suchlike constructions of walls, columns, cornices, doors, windows, and arches could create the suggestion of separating the real space of the painted room from realms beyond it that is outside the space the paintings are adorned with. From the beginning, constructional elements were combined with or used next to motifs alien to architecture, e.g., repetitive patterns similar to wallpaper (e.g., Oplontis: Thomas 1995, Fig. 102), monochrome panel decorations, or consisted of fancy garden vistas and large landscapes which, like the façades, seemed to exist outside the real space. Many painted façades contain living creatures: in the first phases small animals and later on larger human figures moving around within the architectural structures. Moreover, all these wall coverings were to be embellished by the imitation and suggestion of artworks, costly objects, and other figural elements (cf. Mulliez 2014). Over the centuries, some of these effects could get more or less attention, or the figural elements could become unrecognizable, but they never completely vanished. The bulk of paintings we know does not show repetitions or copies of wall systems; each decoration is a unique case on its own, of course full of repeating motifs and syntax, as well as color schemes. Painters might have worked with pattern books or basic schemes; at the same time, they invented decorations depending on the space to be decorated, the light, the budget and material available, and the patron's wishes.

Dating Roman paintings with absolute terms is a difficult matter, since there is no linear development of techniques and forms as we know from more or less firmly dated classes of objects like Attic black- and red-figure vase painting. Even the extensive dossier of Pompeii and Herculaneum, ending in 79 CE, contains a great number of problematic cases, especially for the imperial period, partly because of the dramatically bad excavation methods due to which substantial data went lost. It is an ironical situation that the fragmentary paintings found in many excavations scattered over the Roman Empire often are much better dated thanks to documented stratigraphy and other chronological indications (e.g., Orba in Switzerland: Dubois 2016). Yet, secure dates are rare and may rely on graffiti and dipinti applied on the painted surfaces. A good example is a graffito in house XII in Glanum (Provence, Southern France) dated 32 BCE and thus an indication of the painting's production before that year (A. Roth Congès in Perrier 2007, 207–220; Barbet 2008, 23). In the Augustan-Tiberian settlement of Magdalensberg (Noricum, modern Austria), a painting is dated to the reign of Tiberius by a graffito (Thomas 1995, 188). A peculiar case forms the imprint of coins from the 1970s in the wet plaster of a room in the House of the Old Hunt in Pompeii (Allison and Sear 2002; see below). Historical dates like the eruption of Vesuvius in 79 CE, the sack of Zeugma in 252 or 253, and earthquakes in Ephesus around 262 provide termini ante quem. If unfinished decorations are found, they may be associated with such a natural

disaster (e.g., House of the Chaste Lovers in Pompeii) or a war making an end to the site (e.g., Dura-Europos in 256–257 CE).

While studying finds in Rome, Mau himself could observe a correspondence between Campania and the center of the empire: his "Pompeian" Style system proved to be applicable there as well. Ever since Mau's seminal book, scholars have used his four "Pompeian Styles" and refined their chronology, yet without radically changing them (e.g., Strocka 1996, 2007; Esposito 2014; Bragantini 2014). Therefore, for the period of ca. 200 BCE–100 CE, we still adopt these "Styles," and the predominance of material from Rome, Pompeii, Herculaneum, and adjacent sites during these three centuries should not prevent us from looking at fragmentary, yet informative patches of paintings from many other sites in the Roman world.

The development of decorative trends as proposed by Mau and followed by most scholars, albeit with modifications, should not lead to a slavish imitation of this model, that is, a development model from simple via complex toward degradation. Extremely simple and very complex mural decorations occur in the same complex contemporaneously and depend on the function and status of the rooms. An illustrative example is the House of Augustus on the Palatine Hill in Rome decorated in the early years of his career, ca. 42–36 BCE (La Rocca 2008; Tomei 2014; Sauron 2016; Pensabene 2017, 43–75): smooth whitewashed walls, with some linear articulation in the secondary room 4, which would – if found elsewhere – be seen as late products, occur next to iconic Second-Style paintings in the representative rooms looking onto the peristyle, and innovative adornments in cubiculum 15, while a small black room has a tiny ornamentation in the guise of Third-Style walls. Finally, a couple of badly lit rooms have white walls adorned with (1) slim architecture combined with open central sections with landscapes and (2) a yellow colonnade which get a certain volume thanks to attached garlands and theatrical masks exposed on the architraves.

Mau did not yet problematize the genesis of the four Pompeian Styles. In more recent times, several proposals have been made to explain them culturally. The only contemporary written testimony, Vitruvius' *De architectura* 7.5.1–2, dating to about 20 BCE, offers a fundamental clue, since it describes the formal criteria of paintings in Roman elite houses and distinguishes a couple of subsequent fashions corresponding with Mau's First and Second Styles: "Hence the ancients who first used polished stucco, began by imitating the variety and arrangement of marble inlay; then the varied distribution of festoons, ferns, coloured strips. Then they proceeded to imitate the contours of buildings, the outstanding projections of columns and gables; in open spaces, like exedrae, they designed scenery on a large scale in tragic, comic, or satirical style; in covered promenades, because of the length of the walls, they used for ornament the varieties of landscape gardening, finding subjects in the characteristics of particular places; for they paint harbours, headlands, shores, rivers, springs, straits, temples, groves, hills, cattle, shepherds" (Vitruvius *On architecture* (Loeb Classical Library) v. 2, p. 103 trans. Frank Granger; on this passage, see Tybout 1989, 55–107; Heinrich 2002, 20–21). For Vitruvius, floor and wall decorations constituted an expression of wealth and power of elite persons who formed their leadership and had established their prestige in the Middle and Late Republic by expanding Rome's power from the area around Rome beyond the Italian peninsula, especially in the eastern Mediterranean. As we know from other branches of art, the Roman conquerors imported Greek-style culture and art from "abroad" into their hometown and applied Greek-style decorations such as mosaics and mural decorations in their gradually expanding residences. Public and religious buildings, both old and new ones, received similar decorations. During the Late Republic, Rome experienced a booming business in building, which has to do with the increase of capital and richness and the need to erect temples and other prestigious monuments to commemorate the military victories.

Development of Decorative Systems

The First Style, also known as Incrustation or Masonry Style, consists of a rendering in shallow

stucco relief of a wall in layers of rectangular marble blocks of standing and oblong shape, subdivided into various horizontal ashlar layers. Cornices, columns, and pilasters enliven the ashlar systems and create the suggestion of colonnades and upper storeys with windows and adorned panels (Fig. 1). Figural elements are scarce but are not entirely absent. The finely made relief decorations were expensive and prestigious commodities, perfectly meeting the elite's demands, and it is striking that in Pompeii, relatively many of them have remained in use up to the end of the town's existence (Laidlaw 1985; Heinrich 2002, 10: 80 houses in Pompeii; cf. L. McAlpine in Lepinski and McFadden 2015, 167–186). The fashion has been associated with the mentioned second-century building boom in Rome (e.g., Elkins 2015, 47–51). The fake marble coatings hid tuff and limestone walls and gave them a rich but, thanks to the absence of further ornamentation, austere appearance. In the eastern Mediterranean, the ashlar blocks, often rendered in fancier colors which can barely be connected with real stone or marble types, are enriched by ornamental details like Lesbian cymatium and other cornice forms (Guldager Bilde 1993; e.g., Tel Anafa, Ephesos, and Pergamon: Rozenberg 2008, 298–309; B. Tober in Zimmermann and Ladstätter 2010, 31–33; Schwarz 2016; Bachmann and Radt 2017, 256–264; B. Tober in Mols and Moormann 2017, 215–219). A striking example is the Tel Anafa decoration from a Late Hellenistic Stuccoed Building, seen by various scholars as a villa, inhabited between 120 and 90 BCE in the environment of Damascus. The opulent and heavy-looking wall decoration contained, among the materials used, particles of thin gold leaves in the Corinthian capitals, which must have made these murals extremely expensive (Fig. 1; see B. Kidd in Lepinski and McFadden 2015, 77–95). A connection with royal palaces in Alexandria (no longer extant, but see Rozenberg 2008, 286–288) and Pergamon (cf. Schwarz 2016) has deservedly been postulated, while for the west we should also take into account the royal town of Syracuse on Sicily conquered in 211 BCE and considered a rich source of inspiration for Rome, as well as Carthage overrun and destroyed by the Romans in

Roman Wall Painting, Fig. 1 Tel Anafa, reconstruction of mural decoration from upper floor room of unknown function from the Late Hellenistic Stuccoed Building (LHSB), late second c. BCE. (Reconstruction courtesy of Benton Kidd, University of Missouri)

146 BCE; here masonry-imitating fragments have come to light (Lancel 1995, 320, Fig. 190). Similar stucco reliefs are known from sites in Sicily and the Italian peninsula, predecessors of the more or less completely preserved First-Style walls in the Vesuvian towns and elsewhere (e.g., Iatas; cf. La Torre and Torelli 2011). They demonstrate that the Pompeian First Style stood in a firmly established Hellenistic tradition. In eastern Spain (C. Guiral Pelegrín et al. in Mols and Moormann 2017, 477–481) and southern France (Barbet 2008, 39), examples stem from the earliest colonized part of Hispania and Gaul, respectively, where the First Style might have existed (especially in sites connected with Carthage) or have been brought by commercial routes from the center. All these western examples including Pompeii are less colorful and less heavy than the contemporary cases in the east.

The greatest innovation which stands at the origin of the Second Style (see Tybout 1989; Heinrich 2002; Perrier 2007), covering the

decades from 90 BCE (Rome) or the 80 BCE (Pompeii) to 20 BCE, is the absence of stucco relief apart from cornices between horizontal zones or at the top of the walls: it constitutes the first phase of "real" Roman wall painting. Second-Style paintings consist of a two-dimensional rendering of what characterizes the First Style, that is, a combination of large blocks or smooth frieze in the dado followed by a central and upper zone with orthostates rendered in various colors, and an upper zone containing three tiers of oblong or – less commonly – standing blocks as in room 45 of the Villa of Ariadne at Stabiae (Fig. 2; M. Grimaldi in Perrier 2007, 177–194), or a smooth plain surface. More simplified is the panel decoration in either two or three horizontal zones, subdivided by colored bands, pilasters, or columns (Heinrich 2002). The "flat" decorations form pure paintings which give the makers a greater liberty to vary with architectural and other elements next to the application of plain surfaces of various dimensions. The oldest example known would be the House of the Griffins on the Palatine in Rome; its rooms were backfilled in later ages and remained preserved for that reason (i.e., Tybout 1989, 373–375; Rozenberg 2008, 311, Figs 3. 280–281; Pensabene 2017, 3–14: maybe slightly later). The most conspicuous, but considerably less frequent, expressions are architectural fantasy façades which appear in the years 60–40 CE and do not adorn specifically big rooms, but those most favored architectonically and functionally by the owners and seen by them as a representative and suitable to receive guests and relatives (Heinrich 2002, 57–67). These "façades" – which have incorrectly determined the perception of the Second Style (cf. Heinrich 2002, 70, note 787) – contain fake openings leading toward an imaginary space beyond the painted (and real) wall. To create these double realms, doors or fences separate the spectators as occupants of the room from gardens, courtyards, or even cityscapes (Fig. 3: cubiculum M of Boscoreale; see on this villa Barbet and Verbanck-Piérard 2013). On the basis of the masonry imitations and the fancy façades, scholars tend to subdivide the Second Style into three or more stages corresponding with their "openness," although the chronological sequence is less rigid than has been presumed. We should not look for examples in real architecture nor try to reconstruct the painted mock architectures in some sort of 3D model, nor connect them with the building boom in the same era (contra Elkins 2015, 40, 42–44; see review by J. Lipps, *BABESCH* 92, 2016, 214–216, esp. 215), since these depictions are

Roman Wall Painting, Fig. 2 Castellammare di Stabia, Villa of Ariadne, Second-Style decoration. (Photo Domenico Esposito)

Roman Wall Painting, Fig. 3 Boscoreale, cubiculum, left wall, now New York, Metropolitan Museum of Art. (Public domain: https://commons.wikimedia.org/wiki/File:Cubiculum_(bedroom)_from_the_Villa_of_P._Fannius_Synistor_at_Boscoreale_MET_DP170950.jpg)

purely fantastic creations. Apart from the *megalographiae* and garden paintings (see below), figural elements tend to remain scarce.

It has been argued that the Second Style in Pompeii was a phenomenon brought top-down by Roman colonists who occupied the town after its definite Romanization in the 80 BCE. This would mean that the fashion originated in the center of power, Rome, and that old inhabitants of Pompeii would not be interested in the new forms. To assume a Rome-centrism in Pompeii only (discussion and evaluation in L. McAlpine in Lepinski and McFadden 2015, 170–171) is unlikely, since this fashion expanded contemporaneously toward other towns on the peninsula and beyond and should be seen as a change of taste occurring simultaneously in other art genres and in literature (Grüner 2004). Moreover, Second-Style paintings are known from numerous sites outside Italy, to begin with some 20 examples in France (Barbet 2008, 40–52; cf. Perrier 2007; La Torre and Torelli 2011). A fascinating example in the Near East is that of residential complexes built and decorated after 30 BCE under a vassal king of Augustus, Herod the Great, who had sojourned for several years in Rome and might have brought painters from the center to Iudaea. They include the Second and Third Palaces at Jericho, the fortress of Masada, and the Herodium (Rozenberg 2008, 333–375; S. Rozenberg in Mols and Moormann 2017, 229–235) and show decorative systems adopting elements from the First, Second, and Third Styles contemporaneously. However, the existence of further examples in the region itself, not tightly connected with Rome, as sources of inspiration rather than the Roman connection, cannot be ruled out.

A peculiarity of Pompeii and the villas in its surroundings – and much less its twin Herculaneum (Esposito 2014, 95–107) – is that there are rather conspicuous remains of First- and Second-Style paintings preserved in buildings functioning until the last days of their existence. Those in Rome are hidden under later layers and will not have been on view, whereas in other sites we possess finds from debris depositions only and do not know how long they were visible. Their presence in the Vesuvian area testifies to their careful preservation (and sometimes restoration, see Ehrhardt 2012) as heirlooms, not only in a literal sense of possession transferred from one to a subsequent generation of one family but also of subsequent owners who

apparently fostered the old murals as a prestigious commodity referring to the previous generations of citizens (see L. McAlpine in Lepinski and McFadden 2015, 167–186).

The classicizing fashion of the reigns of Augustus and Tiberius, ca. 20 BCE–40 CE, that is, Mau's Third Style, gets its full expression in the miniaturization of architectural elements, a reduction to linear motifs which articulate the walls into plain fields combined with vistas through imaginary windows or large figural scenes applied as if they were canvases hung on the wall (Fig. 4; Bastet and De Vos 1979; Ehrhardt 1987; Thomas 1995, 36–78, 172–211; Esposito 2014, 108–132). Third-Style decorations often have closed, that is, dark-colored, lower and central zones articulated by means of thin vertical architectural elements or bands, with an upper zone featuring stylized architectures and human figures against a contrasting, mostly bright plain background. The latter may reflect the vistas of the Second Style, in which the onlooker looks beyond the imaginative separation wall into a fantastic realm. Alix Barbet aptly called this tendency toward flatness a "réaction anti-illusioniste" to the illusionistic world of the Second Style (Barbet 2008, 53).

Good examples are various rooms in the so-called Villa Imperiale which lies on top of and in front of Pompeii's old city wall and under the Julio-Claudian Temple of Venus (Fig. 4). Still simpler, but equally rich thanks to the refined and detailed paint work is the villa found in the village of Boscotrecase, northwest of Pompeii, which is generally attributed to Marcus Agrippa's son Agrippa Postumus, dating between 12 BCE and 7 CE. The decorations were stripped in the early twentieth century and sold, so they are (mainly) in Naples and New York (see, e.g., Anderson 1987; von Blanckenhagen and Alexander 1990; Thomas 1995, 45–51). The tiny architectural elements in the black room 15 – reconstructed from partially cutout fragments in New York (Fig. 5) – possess no volume at all. Each wall has a flattish central niche or window frame adorned with a tiny landscape, whereas the surface is subdivided vertically by tholos-like metallic structures and candelabra supporting yellow Egyptianizing scenes. All these purely ornamental devices produce a bricolage of various origins, e.g., "Egypt" and the agrarian Roman rural realm surrounded by almost abstract forms (on bricolage or mix of elements from various cultural realms, see Versluys 2017,

Roman Wall Painting, Fig. 4 Pompeii, Villa Imperiale, room A, view toward the east wall. (Photo Domenico Esposito)

Roman Wall Painting, Fig. 5 Boscotrecase, Villa of Agrippa Postumus, "black room" (15), now New York, Metropolitan Museum of Art, inv. 20.192.1–11. (Public domain: https://www.metmuseum.org/toah/works-of-art/20.192.1-.8,.10,.11/), 10–1 BCE

221–229). The small tondi on top of the miniaturized candelabra of the north wall has convincingly been interpreted as portraits of Agrippa Postumus' mother Julia and her stepmother Livia, so that the application of these paintings might have been realized in 11 BCE, just after the death of Marcus Agrippa, Julia's husband, and Agrippa Postumus' father (Anderson 1987). Over the years, the Third Style tends to regain more substantial architectural forms, e.g., worked-out central niches and heavier architecture in the upper zones, whereas the complete system remains closed and lacks the corporality of the preceding Second-Style walls.

Popular elements are thin candelabra next to likewise thin and richly adorned columns as vertical dividing elements, which occur for the first time in the Villa della Farnesina in Rome, usually dated in the late 30s or 20s BCE, but probably a decade older in tandem with the House of Augustus, viz., 42–36 (La Rocca 2008; Pensabene 2017, 81). Both in Italy and beyond the quality of many decorations are very high, which tallies with their representative status. Candelabra frequently occur in the northern part of the Roman Empire (Thomas 1995, 27–36: early examples; for Gaul, see Barbet 2008, 61–63, Figs. 57 and 58). Several rooms in a mid-first-century house in Fréjus (Place Jules-Formigé: Barbet 2008, 73–76, Fig. 82) display a predominance of red panels in the main zone, all adorned with miniature candelabra and columns, but lacking figural motifs, with the exception of a garden decoration. There might be some chronological difference between the various rooms, but the owner (or successive owner) maintained this Third-Style look in later decades. From the same era is a house found in Soissons (Rue Paul-Deviolaine; Barbet 2008, 95–98, Fig. 120) in which there are five red and two black rooms, two of which (room II and room IV) definitely are of early fabrication. The red panels suggest pieces of fabric hung upon a blue panel and surrounded by minute ribbons and green garlands, whereas friezes with birds separate these panels from the dado. This fashion of fake tapestry would become a popular Fourth-Style element but might be an early experiment in this context.

The two-dimensional character of the Third Style, with less heavy architectural elements and almost complete absence of marble veneer, has

been connected with Augustus' wish to observe austere *mores maiorum* and to abstain from ostentatious luxury. While this may be true for the formal aspects, showing a certain soberness, many decorations look simpler but are extremely expensive thanks to the use of precious paint material and the application of refined ornamentations by skillful decorators. What is more, if one wants to connect this tendency with Augustus' own sobriety, one should be puzzled, since his own building projects, both public and private, are not simple at all. Yet, the remains in his own house on the Palatine (see above) date to his first years of adulthood, around 40 BCE, when he started struggling for power; they are at odds with this simplification but belong to a different approach to displaying power and prestige.

Alix Barbet connects the expansion of the Third Style in Gaul with Augustus' sojourn in Lyon in 16–13 BCE (Barbet 2008, 103–104), but a diffusion via less official channels seems more likely. Augustus was in Gaul to oppress local opposition and, certainly came not as a propagator of culture. Since motifs of the Augustan fashion also were in circulation in other zones of the growing empire (e.g., Cologne, see Thomas 1993, 85–87, pl. 1), this explanatory model cannot be substantiated.

A sort of transition to the Fourth Style, taking place in the age of Caligula and Claudius, is formed by the House of Marcus Lucretius Fronto in Pompeii, where purely ornamental motifs are combined with tentative vistas, and the House of the Tuscan Colonnade in Herculaneum, with its more articulated architectural forms in the upper zone of the oecus (Fig. 6; Esposito 2014, 128–130, pls. 92–93). These decorations constitute a hybrid transitional set of decorations with characteristics of both the Third and Fourth Styles, which – among other reasons – tend to be more critically approached than the First and Second Styles (cf. assessment in Esposito 2014, 133–147).

The Fourth Style is the most puzzling phase in first-century CE painting developments (see inter alia Thomas 1995, 79–169, 211–320; Mols 2007; V.M. Strocka in Zimmermann 2014, 29–40; Esposito 2009, 2014, 151–200). Despite the

Roman Wall Painting, Fig. 6 Herculaneum, House of the Tuscan Colonnade, oecus 5, south wall. (Photo Domenico Esposito)

great bulk of material known from many sites, it is difficult to establish a firm chronology on the basis of stylistic and/or formal developments. We cannot observe a clear-cut formal development, similar to the Second and Third Styles, on the basis of rendering architectural elements or other forms or on the degree of openness of the decorative systems. Murals attributed to this phase, which runs from the Claudian era up to the beginning of the second century CE (on the extension beyond 79 CE, the destruction date of Pompeii, see Mols 2007; S.T.A.M. Mols and E.M. Moormann in Zimmermann 2014, 105–111), display forms deduced from all previous stages, including substantial next to miniature architectural elements, more or less organized in open façade-like structures as well as closed panel schemes and zones filled with marble veneer (Fig. 8). They show what Renate Thomas has aptly called a "style pluralism" (Thomas 1995, 169). Representations of First-Style-like ashlar blocks occur in a much simpler form, i.e., as a plain, white field subdivided into blocks by simple red or black lines, next to fine *opus sectile* imitations.

Architectural schemes may cover entire walls or large parts thereof in compositions often called *scaenarum frontes*, after the stage façades of the Roman theatres; although as in the Second Style, there is no immediate relationship between the real and painted architecture. Structural elements form sections between panels and constitute an articulation of the wall into a set of large and small built arches and niches. Good examples of these, in German aptly called *Prunkfassaden*, have been preserved in Nero's Golden House, which might be the first instance of a popular fashion expanded both in Italy and beyond (Fig. 7; Meyboom and Moormann 2013, 90–91; Dubois 2016, I, 175–177). European examples include façades in Calais (France: Barbet 2008, 3) and Dover (Great Britain: Davey and Ling 1982, 111–114;

Roman Wall Painting, Fig. 7 Rome, Golden House of Nero, corridor 50, fantasy façade, now faded, here reproduced after a late eighteenth-century colored print. (From Meyboom and Moormann 2013, II, Fig. 50.5)

Philp 1989) dating to the middle of the second century CE.

Often, we observe a combination or mix of different forms, as if the painters used cuts from master models like ornamental façades and panel decorations (Peters 1982). A new element is the insertion of mock fabric draperies instead or on top of rectangular panels in the middle and upper zones, adorned with embroideries (Fig. 8). Behind and between the hung tapestries, architectural elements and ornaments fill the surface as if the painters felt a *horror vacui* and ventured to fill all spaces otherwise left empty. Textile borders also substitute for the frames around the panels or run on top of them. Due to this potpourri of forms, it is impossible to connect the Fourth Style with a determined primary location or context, let alone a specific creator, although Rome's imperial elite is the most likely candidate (V.M. Strocka in Zimmermann 2014, 32), while the rationale of this wild mix of forms is likewise difficult to define. It has been argued that the Fourth Style was an invention made at Nero's court in Rome, which theory reflects a traditional notion that new fashions in art were created in the highest circles of patrons such as courts or urban elites. Given the fact that wall decorations made according to this fashion are known from earlier monuments, especially in Pompeii, this assumption is unrealistic (Thomas 1995, 79; Meyboom and Moormann 2013, 23–24). At the same time, it would be a reaction on the Third Style's austerity (e.g., Thomas 1995, 106), but Third-Style-like systems frequently occur in the Fourth Style. Another point brought forward is that the Fourth Style shows a certain degree of neglecting pictorial qualities and is artistically less convincing than its predecessors; this opinion started with Mau (Mau 1882). A strong impetus to find this fashion below good taste originates from Paul Zanker's influential article on the imitation of villa culture of the late Republican period during the Neronian and Vespasianic era in Pompeii. He argued that the predecessors had good taste, whereas the followers were nothing but tasteless nouveaux riches (Zanker 1979; also, in later publications). Apart from the fact that, in a technical sense, Fourth-Style paintings are not worse (or better) than the previous ones, this negative estimation implies a scarcely enlightened assessment of the Neronian and Flavian period as a whole. These intimations seem strongly conceived by the negative image of the notoriously badly esteemed emperors Nero and Domitian rather than based on a meticulous analysis of their era's culture.

Some scholars have tried to distinguish between Neronian and Flavian painting, in which reasoning the connection of style forms is once more connected with the personalities of

Roman Wall Painting, Fig. 8 Pompeii, House of the Old Hunt, tablinum 11. (Photo Domenico Esposito)

these emperors (e.g., Thomas 1995, 136–166; Strocka 2010; cf. Esposito 2014, 151–152). The Flavian decoration would be more "baroque" and richer of lavish elements, although the mature Fourth Style, which is the late Neronian phase, as we can see in first instance in Nero's Golden House on the Oppian Hill, already displays a wide array of possibilities. Although many shapes encountered in this palace – ornamental façades (Fig. 7), panel decorations, *aediculae* and parts of them subdividing panel systems, repetitive patterns, embroideries – are found in buildings elsewhere in more or less the same time (see the analysis of Pompeian decorations in Thomas 1995, 134–136), the lack of firm chronological criteria for the latter group of monuments makes such an assumption rather shaky. In the Vesuvian area, the few dated complexes comprise the not yet completed decorations in various houses, e.g., the House of the Chaste Lovers in Pompeii. An extraordinary case is the aforementioned set of stamps of datable coins in the wet plaster of the atrium in the House of the Old Hunt in Pompeii (Allison and Sear 2002, 83, Figs. 263–271; cf. Thomas 1995, 151–152). A group of heavily adorned decorations in Herculaneum's public and sacral edifices of the *Augusteum* and the unfinished *Aedes Augustalium* in Herculaneum form a Flavian set (Moormann 2011, 119–137; Esposito 2014, 45; for houses ibidem, 158–163). Here architectural elements are plastically rendered, there are vistas through open windows, and the color scheme is abundant. A group of decorations attributed to a large workshop named after their principal project, the Vettii workshop, seems also to have been active in the last decade of Pompeii's existence (Esposito 2009, 49–132, esp. 57; cf. Moormann 2011, 149–162, on this workshop's paintings in the Temple of Isis). Nevertheless, even firmly dated walls do not yet help us very well to define different stylistic phases within the Fourth Style. Experts have to rely on stylistic and formal associations, which often are rather arbitrary and subjected to connoisseur-like estimations. Yet, the paintings attributed to this latter phase are similar to the preceding decorations albeit richer and, especially in respect to the architectural elements, more complicated. Wallpaper patterns and marbling are present to a larger extent than before.

Whereas Rome itself has little on offer beyond the complex of Nero's Golden House (see Meyboom and Moormann 2013), in Rome's harbor city Ostia, the painted material known was until recently limited to material from the second century CE onward (see below). Thanks to recent stratigraphic excavations and research on fragments found during the two previous centuries, one can now observe the same trends as in Rome and the Vesuvius area (Falzone 2007, 29–47; several contributions in Mols and Moormann 2017, 335–361). The quality of these murals seems to have been extremely high, as one can see in situ on the red paintings of the temple of Bona Dea dated to the early first century CE (Falzone 2007, 41–42; Moormann 2011, 67–68; S. Falzone in Mols and Moormann 2017, 337). The same is true for complexes elsewhere in the Roman world, where a common decorative language is recognizable.

From the Fourth Style onward, the application of mock marble veneer never vanishes from the painters' repertoires. The consumption of marble plaques at a large scale occurs for the first time known in Nero's Golden House in Rome, where wall painting has a secondary value in the principal rooms, because these could be clad with marble up to their entire heights or lower sections (Meyboom and Moormann 2013, 74–76, 84–87). Elsewhere, however, the use of real marble is much less lavish, so that painting remains an indispensable commodity for the furnishing of interior space; these veneer depictions were no mere cheap substitute. A couple of times one finds combinations of real and mock marbles in the same room, and in the second and third centuries, the rendering of costly opus sectile in painted form demonstrates the careful and far from easy and cheap-looking application of imitation marble patterns. The final impression seems to have become much more important than the materiality, which corresponds with one of the principles of Roman mural painting: imitation and *trompe l'oeil*. Initially, marbling as well as the use of real marble is limited, especially in the Vesuvian area up to 79 CE, to the dado, but

gradually it appears in the form of orthostates or pilasters occupying the main zone, the orthostates being equivalents of standing marble blocks or panels made of marble slabs, in all cases framed by strips of different marbles (for Ostia, see Danner 2017, 94–98).

Our knowledge of second- and third-century painting, both in Italy and outside, is disparate (most recent overviews: Ling 2014; Dubois 2016, I, 137–191). In the sense of decorative systems, there are no radically new trends or "Fifth-Style" decorations differing conspicuously from the Fourth Style. It has been observed that post Fourth-Style painting grows less elaborate and less expensive in the run of the imperial period (Ling 2014, 371–372). This would correspond with the increasing application of marble veneer as well as wall mosaics on the walls after the example of the imperial palaces in Rome, to begin with the Golden House (see above). Even if, indeed, many decorations show a lower artistic level than earlier murals, this suggestion is at the same time contradicted by fine and well-executed paintings. The second and third centuries show the same wide array of possibilities as the Fourth Style and might rather constitute a consequent development of the Fourth Style. The negative judgment might originate from the similar thoughts on that fashion (see above). The Roman Empire which partly enjoyed a flourishing and booming era was partly struck by political turmoil and economic inconsistency, for which reason the economic base of private culture greatly differed regionally and in time and affected artistry and craftsmanship. Architectural systems exist, especially during the second century, next to panel decorations and allover patterns or combinations. Panel decorations gradually become the dominating fashion. The schemes of juxtaposed panels can be enlivened by the intersection of vertical architectural mini-vistas, candelabra and foliate patterns, as well as the adaptation of contrasting color schemes. What is more, the frames may be adorned, and the panels themselves can contain small figural scenes or vignettes in the form of standing human and divine figures, sometimes explained by added texts in the form of *tituli picti* (see Dubois 2016, I, 336–343).

In Rome, decorative systems from the first half of the second century still display combinations of plastically rendered architecture and flattish panel systems. Although lost and only known from Carlo Buti's fine watercolors, mention should be made of murals from a Roman house found in the late eighteenth century not far from the modern Stazione Termini in Rome, in the Villa Negroni. Buti's images show semicircular decorations stemming from the upper parts or lunettes of vaulted rooms, with *aediculae* and subtly colored surfaces, embellished with large mythical scenes, which seem to date to the 130s (*Antiche Stanze* 1996, 29–35; Ling 2014, 375). They display a great preference for large yellow and red planes combined with smaller sections in other colors and with columns and architraves.

During a radical Hadrianic transformation (Falzone 2007, 52–54), Ostia was more or less rebuilt and got apartment buildings, the *caseggiati*. Decorations often show a colorful use of red and yellow surfaces (panels or interiors of *aediculae*) combined with architectural elements as vertical dividers, e.g., in the House of the Muses. Dadoes may contain the same color scheme panels or marbling (Falzone 2007, 51–95). Whereas the later second century shows both voluminous and stylized architecture, with a peculiar combination of red and yellow panels filled in with sketchy architecture, tiny scrolls, and thin frames such as those in the House of Painted Ceiling and the House of Jupiter and Ganymede (Falzone 2004, 61–74, 95–101, 2007, 107–124; Dubois 2016, I, 167–168), the third century marks the presence of linear, highly "abstract" structures. Thin festoons, floating figures, and diverse ornaments enliven the walls. A further simplification brings new schemes and color combination in the subsequent era, with predominantly white-grounded decorations (Ostia, *Caseggiati* of the Sun and of Themistocles, see Falzone 2004, 143–165, 174–176; cf. Dubois 2016, I, 158–167). As in the Third Style, architectural details make place for "geometrization" (Falzone 2004, 190) in linear systems, creating the aptly called "Linear Style" or, less ideally, "Catacomb Style" (after occurrences in Rome's underground cemeteries) in the late second

century (see Falzone 2004, 192–197; Dubois 2016, I, 144–146). The houses in Ostia mostly do not show more than one painting layer per room, which either means a unique phase lasting for many decades or a radical replacement of an older decoration that was completely removed, whereas between the rooms there can be considerable differences (Falzone 2004, 169–175). There reigns a certain hierarchy between the rooms, so that the more important ones display more color and architectural elements than secondary rooms. A few wall-covering scenes represent garden depictions and mythological figures like the marine Venus in a third-century house under the Church of Santi Giovanni e Paolo in Rome (Ling 2014, 414–419, esp. 414–415, plate 9.16).

There is no overview available of the material from the Roman provinces as a whole (see a summary in Ling 2014), but a couple of towns and villas for which extensive corpora are available should serve as representative cases. Architectural schemes could be as elaborated as the Ostian examples. In Britain, for instance, there are remains in situ in a Roman house in Dover dated to the Severan age (Philp 1989; Dubois 2016, I, 176–177, Fig. 12) and in a house in Leicester dated with less substantiation to the middle of the second century CE (Davey and Ling 1982, 111–114; 123–131; cf. R. Thomas, *Bonner Jahrbücher* 183, 1983: 905). They contain plastically rendered architectural elements framing panels and adorned with objects which seem exposed within the painted realm.

In Germany the ancient town of Cologne offers a wide array of subsequent painting phases which in general match developments in the center of the empire. Panel decorations with candelabra in the division bands often display a high quality (Thomas 1993, 44–50). A house decoration in the area of the Cathedral from the Flavian era comprises richly elaborated candelabra on black vertical panels framing red panels (Fig. 9; now Römisch-Germanisches Museum Köln; see Thomas 1993, 44–46, 177–194). The candelabra are peopled by mythical figures maybe inspired by Ovid's *Metamorphoses* (R. Thomas in Mols and Moormann 2017, 493–500) and enriched by vegetal bands and garlands. The Cologne scheme is found elsewhere in the northern provinces; see the Gallo-Roman temple of the Flavia era in nearby Elst (The Netherlands: Moormann 2011, 91–92) and a house in Verulamium (Great Britain: Davey and Ling 1982, 188–191), while we encounter similar candelabra in Carthage (Barbet 2013, 38–39, Figs. 36–37; 54–55, Figs. 57–58). They

Roman Wall Painting, Fig. 9 Cologne, wall with candelabra from House H/1 of Domviertel, now Cologne, Römisch-Germanisches Museum. (Courtesy Rheinisches Bildarchiv, Cologne)

differ from the Italian examples in that they adorn dark-colored strips framing monochrome panels, frequently without the addition of architectural elements.

In the second century, there are various examples of decorations with larger and smaller figures in various registers. Debris from the Roman villa of Maasbracht (The Netherlands, see Swinkels 2017, here Fig. 11) contained fragments of a grand decoration, in three registers, with gladiators, functionaries, or patrons acting in or near the villa itself, as well as mythical figures like Apollo and Venus, some of them adorned with *tituli picti*. On the basis of both archaeological and comparative material, they should date to the late second century CE. A similar set of magistrates is known from a watercolor documenting a lost decoration in the House of the Boar Hunt in Carthage, probably applied in the late second or early third century (Barbet 2013, 40–42, Figs. 41–42). In Rome, there are examples from a luxurious house annex bath suite from the mid-second century and slightly later CE found on Piazza del Cinquecento, showing bathing women and personnel (*Antiche Stanze* 1996, 122–130, 162–166). In the large villa of Piazza Armerina in Sicily, principally known for its figural mosaics, there are figures of this kind on wall paintings from the early fourth century (J. Valeva in Mols and Moormann 2017, 63–68), whereas Christian influence can be found in panels with praying humans from the Romano-British villa in Lullingstone dating to the middle of the fourth century (Davey and Ling 1982, 138–145).

The Metropolis of Ephesos on the western shore of Asia Minor has some remarkably well-preserved complexes of painting covering high and late antiquity. Researchers from the Austrian Archaeological Institute executed longstanding explorations in two house blocks situated on the north slope of Bülbüldağ, commonly known under their German name as Hanghaus 1 and 2. A corpus of the paintings was edited in 1977 by Volker Michael Strocka, which together with a volume dedicated to the houses' mosaics provided the first full documentation of murals in the eastern Roman Empire. Strocka articulated various phases over a very long period, viz., the early first century until an earthquake in 612/614 CE, and distinguished various fashions, e.g., a simplified white panel "style" in late Antiquity next to a richer set of polychrome decorations, embellished by the insertion of figural scenes and large and heavy ornamental elements like garlands carried by putti. Re-examination and reassessment of this material in the 1990s caused a chronological landslide: on the basis of coins and graffiti mentioning *assaria*, coins used until 268 CE, the life of the complexes resulted to have lasted until a major earthquake around 262 (Krinzinger 2002; on paintings ibidem N. Zimmermann, pp. 101–117; accepted by Strocka 2002; now Zimmermann and Ladstätter 2010, 45–49, 81, Figs. 54, 117–119; Zimmermann 2018). The new chronology has met with approval and got substantiation by new investigations and elaborations of the finds at large in the more recent volumes of *Forschungen in Ephesos* dedicated to the seven single houses within Hanghaus 2. In correspondence with four (re)construction phases, paintings from three up to eight layers thick, corresponding with various subsequent refurnishing campaigns, can be distinguished. Panel decorations form a constant theme. There are two series of red panels in the main zone from the Trajanic era separated by black bands. In one room they were adorned with vignettes featuring, among others, Socrates and the Muse Urania, while the upper zone contained mythical scenes circling around Achilles. The learned literary touch of this well-made decoration is evident. In later phases white decorations dominate, although colored ones are not entirely absent. The upper zones contain simply rendered architectures recalling those of Third-Style ensembles in Italy. The panels are enlivened by a wide array of vignettes: children as gladiators, putti, busts of the Seven Wise Men, Muses (Fig. 10), fish, and birds. The vertical bands contain garlands and candelabra, and the dadoes are often filled with elaborate marbling, sometimes in combination with real veneer. The Ephesos paintings show a mix of local trends and impulses from the west in the first half of the second century, especially from Rome and Ostia, where specific correspondences can be observed, which might have to do with personal contacts of elite Ephesians with the

Roman Wall Painting, Fig. 10 Ephesus, Hanghaus 2, Wohneinheit 3, room 12, panel decoration with Sappho, Apollo, and Kalliope as vignettes in the main zone and idealized heroes in the upper zone, second quarter of the third century. (Photo N. Zimmermann, © IKAnt ÖAW)

Roman Wall Painting, Fig. 11 Maasbracht, Roma villa, reconstruction of a wall decoration from around 200 CE, with mythical figures in the dado, gladiators in the main zone and daily life scenes in the upper section. Reconstruction Louis J.F. Swinkels. (Courtesy L.J.F. Swinkels)

Empire's capital, but do not develop afterward new ways of decoration and tend to stick to flattish panel ensembles (Zimmermann and Ladstätter 2010, 120–123; Zimmermann 2018).

Rescue excavations at Zeugma in eastern Turkey in the late 1990s brought to light various houses on a slope similar to the Ephesus Hanghäuser, decorated with mosaics and paintings. Due to the construction of the Bireçik Dam in the Euphrates destroying the site, these items were removed in 2000 and brought to the Archaeological Museum in Gaziantep. While the mosaics

mainly date to the late second century, most paintings decorated the houses in their last decades, just before the town's destruction in 252 or 253 CE by Sasanians (Aylward 2013, I, 9, 12, 29–31; on the paintings Barbet et al. 2005 and B. Bergmann in Aylward 2013, I, 168–177). There are similarities to the Ephesus material such as the use at large scale of marbling dadoes, mock opus sectile panels, and white panels filled with standing figures in the main zones. The upper zones are all lost. Some rooms have different strata of subsequent, but as yet barely datable phases. An extremely colorful ensemble adorned the representative room P11 of the House of Poseidon: on top of a protruding base, male figures, probably representing, servants, ca. 125 cm tall, are standing inside arched niches between which there are fake miniature doors. They remind us the Second-Style *megalographiae* and, more likely, reflect the attendants in the aforementioned bathhouse rooms at Piazza del Cinquecento in Rome, dated around 180–200 CE. A panel decoration of room P26 of the House of the Euphrates dated to ca. 220 has rectangular panels occupied by seven mythical women; two have their names written next to them (viz., Deidameia and Penelope). Strikingly, just as six unidentifiable women in room P23 of the Poseidon House, the figures are too big for the panels so that their heads cut the upper frames. Various buildings, mainly religious ones, in the Syrian town of Dura-Europos show a bricolage of various elements by which the results, e.g., the lavishly decorated Jewish synagogue and the Mithraeum, are incomparable with material from the mid-third century in the Near East (Moormann 2011, 189–201; Kaiser 2016). Figural scenes dominate.

Roman North Africa has been partially studied well. Thanks to Alix Barbet's monograph on some 20 sites in the area now covered by Tunisia, we glean some general tendencies which partly tie in with the developments in other parts of the empire (Barbet 2013). Few wall systems can be reconstructed on the basis of both material in situ and fragmentarily preserved so that we retain an extremely unsatisfactory image, not ameliorated by the likewise bad chronological anchoring of the greater part of the material. Mosaics often serve as comparative material and fixed points, but this dating method is not entirely conclusive, since floors could have a longer life than paintings and serve various generations, getting new paintings as companions in the run of time. The material assembled shows the same motifs and structural elements as in the center of the empire. Due to the fragmentary state of preservation, almost no complete buildings can be studied in detail. A house in the Theatre quarter of Thysdrus contained a set of a no longer existing, extremely colorful (and maybe precious because of the pigments) house with predominating panels in red, vermillion, green, and mixed marbling fields, sometimes adorned with vignettes. A plaque preserved in the El Jem Museum, probably from the same site, has a white background and contains a rectangular panel with a Diana or Amazon, placed on top of a sort of stretched veil similar to those in Pompeii. Barbet tentatively dates the decorations to the early and middle of the third century CE, but unfortunately, we have neither further clues nor parallels to substantiate this chronology (Barbet 2013, 205–218, Figs. 292–311). Yet the lack of depth and linearity of figure and surrounding motifs might plead in favor of this suggestion.

Context

The decoration fragments known from the Roman world belong to or stem from various sorts of buildings: mainly houses and villas, less frequently baths, tombs, temples, and public buildings. Whereas Vitruvius gives very brief rules about the décor suitable for various spaces (cf. Tybout 1989, 71–77), he "applies" these rules only to the houses of the Roman elite, belonging to men who had to receive guests and to display wealth and power. In a way, these remarks are out of order, since the elite in his day had to be subordinate to the emperor and no longer capable of taking vigorous decisions. For the Republican period, we see a display of wealth in Pompeian houses by means of paintings, but the sizes of the houses appear to be less important than one is tempted to assume (see Heinrich 2002 and L. McAlpine in Lepinski and McFadden 2015, 167–186).

The connection between function, form, and architecture does not allow for establishing substantial differences between building categories. Most buildings do not contain specific characteristics to discern systems or schemes peculiar for a determinate sort of buildings. Houses – much better known than other categories – are decorated in the same ways as temples or public buildings. That means that, apart for shrines of more or less closed religious communities like Isis and Mithras worshippers, temples were painted by the same painters and with the same templates as private contexts (cf. Esposito 2009 for workshops and Moormann 2011 for temples; examples at Dura-Europos, see Kaiser 2016). If archaeologists find painting fragments, they will rarely be able to establish the room's and building's specific parameters on the basis of this material only, unless evidenced by specific iconographic or textual elements.

Figural Systems and Iconography

As mentioned above, the First and Second Styles tend to remain devoid of living creatures occupying the spaces represented (Figs. 1, and 2). In Second-Style decorations, figural elements gradually become important embellishing items (Fig. 3). There are not yet framed figural scenes, while we know a small, but fascinating set of figural friezes of the Second Style similar to historical reliefs like those of the Ara Pacis Augustae in Rome (12–9 BCE), mostly dated to the middle of the first century BCE. On the basis of Vitruvius, these decorations are called *megalographiae*, in singular *megalographia*, referring either to "painting of large figures" or "large-size painting." The first interpretation entails figures moving or standing on a podium, which is the top of a plastically rendered protruding dado, against a set of imitation marble panels (overview: Bragantini 2014, 311–316). The figures are rendered as living persons and seem to represent acting persons or *tableaux vivants* (as if they, indeed, were actors on a stage). Unfortunately, their iconographies are elusive, so that the manifold interpretations of various complexes would leave the onlooker rather confused about their meaning. The most puzzling examples are a frieze in room 5, a banquet room, of the so-called Villa of the Mysteries, painted around 60 (D. Esposito in Perrier 2007, 450; Bergmann 2007) featuring as the protagonist a drunk Dionysus lying in the lap of Ariadne or Aphrodite, often interpreted as religious or mystical scenes, and a now-dispersed set of personages from the Villa of Publius Fannius Synistor in Boscoreale seen as either historical or mythical personae (Barbet and Verbanck-Piérard 2013). The lack of well-interpreted comparable instances enhances the difficulty of interpretation.

In painting beyond Italy, large-size figures are often also called *megalographiae* (e.g., figures in Roquelaure from the early first century CE (Thomas 1995, 23 Fig. 132; Barbet 2008, 89–92). Indeed, if we take into account "large figural paintings" as *megalographiae* (see Dubois 2016, I, 200–202), we encounter many more genres of wall-covering figural scenes from the late Second Style onward, to begin with Augustan garden vistas adorning interior spaces. Early examples are the magnificent subterraneous room from the Villa of Livia at Prima Porta, north of Rome, and fragments from the Villa della Farnesina (both exhibited in the Palazzo Massimo alle Terme in Rome). One wonders what they meant to be: gardens seen beyond the real space through imaginary windows or, as in the Villa of Livia, from within an artificial grotto whose rocky edge is represented on top of the garden representations. They clearly had to embellish the private sphere by creating a relaxed atmosphere (Thomas 1995, 71–72). While they cover walls in rooms during the late Second and the Third Styles (e.g., House of the Orchard in Pompeii), they also adorn open spaces of gardens and courtyards from the middle of the first century CE onward all over the empire, such as in Gaul (Barbet 2008, 295–304) and Asia Minor (e.g., Pergamon, House of Attalus). In a peristyle of house 4 of Hanghaus 2 in Ephesus, dating to the middle of the second century, a *locus amoenus* was created, with real and fake marble dadoes and gardens adorned with statues both painted and real (Zimmermann and Ladstätter 2010, 88–90, Fig. 138; 131–132, Fig. 243). Some painted gardens are occupied by large mythical figures, such

as the Orpheus in the House of Orpheus in Pompeii and the Aphrodite in the House of Venus in the Shell in Pompeii (M. Carucci in Mols and Moormann 2017, 295–300). Alternatives comprise landscapes filled with wild animals, seascapes, Egyptianizing watersides, and villa landscapes. Large mythical and genre scenes cover entire walls or complete zones in later centuries in houses in Ostia, Rome, Ephesus, as well as Libya, where compelling examples of gladiators and hunts are known from houses and bathes in Silin and Leptis Magna from the late second and early third centuries CE (B. Bianchi in Mols and Moormann 2017, 103–106) as well as from northern sites like Cologne and Maasbracht (Fig. 11; see Swinkels 2017, 108–112). Hunting scenes and domestic occupations depicted in the Roman provinces have been interpreted as examples of appropriation of Roman habits by local grandees, an example of which might be the representation from a house in Colchester, Britain, dating to the late first century CE (Davey and Ling 1982, 42, 99–101). In a few cases, these elite people could have practiced commerce, for instance, trading animals for the games in the Colosseum in Rome, or for amphitheaters elsewhere. Although it seems superfluous to apply depictions of what happens in the specific places, in this case of animal and gladiator games, some amphitheaters possess them. A lost example that was documented briefly after its discovery is the amphitheater of Pompeii, which had elaborate Flavian paintings on the parapet walls of its arena. A similar case is that of Uthina in Tunisia (Barbet 2013, 93–98, Figs. 111–117) where some scenes bear the names of the hunters. Barbet remarks that there are, as in many other cases, no sound dating criteria for Uthina; the second century CE seems most likely (Barbet 2013, 95).

From the late Second Style onward (e.g., House of Livia on the Palatine, maybe rather a sacral building (see Pensabene 2017, 81), and the Villa della Farnesina, both in Rome), large figural scenes occupy the central niche or panel of the flattish decorative ensembles (Fig. 4). At the beginning of the first century CE, these scenes include atmospheric landscapes populated by mythical figures. In the Villa Imperiale (Fig. 4), the three scenes illustrate episodes from Cretan mythology: Theseus appearing after killing the Minotaur, Theseus abandoning Ariadne on Naxos, and Icarus falling down after his escape from the Labyrinth. Sometimes the same protagonists appear twice within the same image, expressing two subsequent actions within one myth in what is called a *narratio continua* or continuous narration. On the Polyphemus scene from the Villa at Boscotrecase (von Blanckenhagen and Alexander 1990, 28–33, pls. 42, 44–45), Polyphemus sits on a rock while playing the syrinx to – unsuccessfully – attract Galateia who passes riding a sea creature. In the background, the same cyclops throws a large stone to a vanishing ship, obviously that of Odysseus. This story, mixing the old epic *Odyssey* and Theocritus' *Idyll* 7 (and the contemporary record in Ovid, *Metamorphoses* 13.750–768), shows the refined combination of literary genres. On one of the other walls in this room, the story of Perseus and Andromeda was likewise represented in continuous narration. Next to large panels, there are smaller figural scenes as adornments of the decorative schemes from the late Third Style onward. Their number can differ largely per room, but they form integrated parts thereof. It has been a question of debate whether sets of mostly three mythical scenes constituted iconographically thematic combinations or that stories were applied at random. Over the last years, scholars tend to recognize formal aspects uniting them rather than content: figures are represented in similar postures or the scenes play out in similar backgrounds like the seashore or a woodland (Hodske 2007; Lorenz 2008). Surprisingly, many mythical figures are shown in frontal nudity, which used to shock Romans in "everyday life" but pleased them in art; viewers could make their own associations as to the contents (S. Pearson in Lepinski and McFadden 2015, 149–166). A certain degree of erotization comes to the fore in these nudes as well as in explicit erotic couples who appear in diverse contexts and have been connected with erotic *tabellae* described by Ovid (*Tristia* 2.521–530; see Grüner 2004, 211–218). Popular are genre scenes, representing land- and seascapes, still lives, and daily life occupations, but we rarely encounter scenes intimately related with the

houses' patrons. There is a striking difference between Pompeii and Herculaneum: in Pompeii figural scenes are much more frequent than in the sister town, which can be explained by the fact that the Herculaneum complexes unearthed belong to the richest category of private dwellings, in which real artworks will have had a place of pride. This was also true in large palaces in Rome like Nero's Golden House and Domitian's Domus Flavia (Fig. 7).

Framed scenes tend to become less frequent in Roman wall painting from the late first century onward. A set of mythical figures from Villa Negroni in Rome (see above) include couples of mythical figures, like Adonis and Venus, Mars and Venus, and Bacchus and Ariadne, as well as still lives and landscapes (*Antiche Stanze* 1996, 29–35). In other parts of the Roman Empire, we see the same tendency. A Roman officer of the time of Emperor Commodus in Echzell (Germany) apparently ordered a fine set of mythical images framed by opus sectile imitations of Amazon shields. The scenes include Europa, Perseus, Theseus slaughtering the Minotaur, and Daedalus and Icarus (now in Saalburgmuseum, Bad Homburg; see M. Fuchs in Mols and Moormann 2017, 483–488). Unframed figural motives and scenes become integrated parts of the wall decorations, in the way of the former *megalographiae*, or occupy entire wall zones.

Painters and Workshops

As a rule, the material from antiquity we possess is the product of anonymous artisans. In late Antiquity the terms *pictor parietarius* and *pictor imaginarius* are used to indicate wall and figure painters. In written descriptions of artists, mainly those of Pliny the Elder's *Naturalis Historia* (book 35), many names of painters are transmitted, but none of them is known thanks to his or her own original work, mainly due to the fact that most of them were panel painters rather than mural decorators. In extremely few cases, we have the graffito of a person, or we can connect a name transmitted in literature with a still extant complex. An example of the latter category is Famulus who should have worked in Nero's Golden House between 64 and 68 and whose hand has tentatively connected with scarce remains in the pavilion on the Oppian (Pliny, *Naturalis Historia* 35.120; Meyboom and Moormann 2013, 61–62).

The organization of painters' workshops is not described in ancient sources apart from Vitruvius' mention of *pictorum officinae* (*De architectura* 6.4.2), so that it is a bone of contention whether they really existed or that the individual workmen executed tasks in a loosely organized form. In few cases specialists are capable of recognizing corresponding features like color palette, stylistic particularities, iconographical details, and repeating fill motifs, which betray a connection between the works in one complex (e.g., Nero's Golden House, see Meyboom and Moormann 2013, 54–68) or in one town (Pompeii between 62 and 79 CE, see Esposito 2009). In Herculaneum the painters active in the House of the Mosaic Atrium formed a unique group, also active in most other houses and displayed a wide array of painting modes and levels, from complicated to simple (Esposito 2014, 177–200). On the microlevel, individual painters working in one piece have been individualized a couple of times (cf. Esposito 2009). Outside Campania and Rome, studies of this kind necessarily remain few due to the usually fragmentary status of the decorations (but see on Ephesos Zimmermann and Ladstätter 2010).

Technique

Roman mural paintings were usually executed in the fresco technique, i.e., applied onto a wet preparatory layer or more layers (Vitruvius, *De architectura* 7.3.6–7). After the application of a couple of base layers, the wet top layer was applied just before the painter started his work. Therefore, one may observe the portions prepared to be filled in in one working session or day, called in Italian *giornata*, or corresponding with a division into horizontal scaffolding areas, *pontata*. The top layer was just worked before applying the paint by a *sinopia* or preparatory drawing and subdivided with scratched and hatched lines, all serving to guide the painter in his work. Pigments were chemically bound with the calcium in the layers of plaster and became very resistant. At

the same time, we observe tempera paintings, made on top of frescoes with binding agents which sometime deteriorate in the run of time and may destroy the underlying paintings.

The pigments used are of mineral or vegetal nature and can be of high resistance, thanks to which quality we still have so many paintings preserved. So, we have minerals red, yellow, and green ochres, black made of burnt bones or wood, the very expensive synthetic vermilion, and likewise expensive Egyptian blue or *caeruleum* (on technique see Barbet and Allag 1972; Davey and Ling 1982, 51–62, with attention for specific local features; Barbet 2008, 25–33; Dubois 2016, I, 59–124; F. Pique, E. MacDonald-Korth, and L. Rainer in Lepinski and McFadden 2015, 57–76).

Romanization

Richard Hingley
Department of Archaeology, University of Durham, Durham, UK

Introduction

This entry addresses the changing meanings of the term "Romanization" since the late nineteenth century. For much of the time between the initial introduction of this concept and the 1960s, the process of Romanization appears to have been viewed in an uncritical light by archaeologists and ancient historians. Romanization was often considered to operate as a relatively simple process through which indigenous societies across Italy and the Western Roman Empire became integrated into a civilized community. During the late nineteenth and early twentieth centuries, the ancient historians Theodor Mommsen (1817–1903) and Francis Haverfield (1860–1919) defined this concept. In many of the works that resulted from the tradition established by these two authors, Romanization was identified as a fairly simple process of social evolution, which derived its logic from the assumption that social change occurred in all societies from a primitive form to a civilized way of living and that this process occurred in a measured and progressive manner. During much of the twentieth century, the theory of Romanization was used to explain the gradual spread of urban life, villas, and "Roman" goods (*terra sigillata*, amphora, coins, etc.) across much of the Roman Empire during the period from the late first century BCE to the third century CE. It was considered that this blossoming of civilization was succeeded by a period of decline that eventually led to the fall of Rome in the West in the early fifth century.

A more critical assessment of Romanization arose as a result the decolonization movements of the 1950s to 1970s, as Western Empires were dismembered. At this time, critical accounts of classical Rome gradually developed which took issue with the ideas of civilization and progress on which the earlier theories of Romanization had been based. At first, these critical approaches focused upon the idea of indigenous resistance to Rome, but during the 1990s, a more focused critique of the concept of Romanization developed in Britain, representing a "postcolonial" turn in Roman imperial studies (Webster and Cooper 1996). Since this time, a number of archaeologists have argued that Romanization theory is too deeply associated with Western imperial discourse to remain a useful term (see Hingley 2005: 2). This argument suggests that,

during the early twentieth century, Romanists took on board contemporary ideas of social evolution and progress and read these concepts back into the evidence derived from the Roman past. As a result, classical texts and the material remains of Roman civilization were interpreted through the lens of a linear and progressive form of social evolution. A number of Romanists have argued as a consequence that the term "Romanization" should no longer be used, and this has, in turn, deeply influenced much of the subsequent scholarship on Roman imperial identities. Despite this, many archaeologists in Europe and the United States of America continue to use the theory of Romanization.

After a consideration of definitions, this entry explores a number of phases in the evolution of the theory of Romanization, although it is important to realize that these do not always represent successive stages in a simple process of the evolution of the theory. Firstly, it addresses the rise of the theory of Romanization in the context of the colonial world order of the late nineteenth and early twentieth centuries. Following this, it explores attempts to provide a rather more decentralized interpretation of Romanization during the 1960s to the 1990s. It then considers the postcolonial accounts that have aimed, since the mid-1990s, to dismiss the concept of Romanization. The section on current debates summarizes recent works that have aimed to provide more nuanced accounts of identities within the expanding Roman Empire. Finally, the current context for studying Roman identities is considered, and it is argued that today, no one explanatory framework dominates the subject.

Definition

The term "Romanization" was first introduced into the English language during the late nineteenth century. It drew upon the common use of the word "Romanized," which has much earlier origins in Europe (Hingley 2008: 436). There is only use of the noun ("Romanization") listed by the *Oxford English Dictionary* prior to the final 15 years of the nineteenth century, and the concept was introduced as a result of the scholarship of the German classicist, Theodor Mommsen, who in 1885 articulated the concept of "Romanisierung" in the fifth volume of his seminal work *Römische Geschichte* (Hingley 2008: 436). The term was adopted and popularized by the Oxford ancient historian Francis Haverfield in his influential work, "The Romanization of Roman Britain," first published as an article in 1906 and republished on several occasions as a small book.

There are many definitions of Romanization, and the meaning of the term has not remained static. The initial idea that a well-defined Roman urban civilization was gifted to the "barbarians" of the Western Empire was long ago replaced by accounts that explored the complexity of imperial relations. For Kathryn Lomas (1995: 109), Romanization means, "The transition [to] a characteristically Roman set of cultural attributes and assumptions, assuming that the speed and mode of transmission and the nature of their reception vary according to the nature of the recipient and the social and economic level at which the transmission operates at any given moment." This makes it evident that Romanization has often focused on the rich and well-connected peoples of the Roman Empire, stressing the material remains left behind by the villa owners, urban dwellers, and soldiers. However, the theory of "osmosis," or trickle-down Romanization, was introduced during the final quarter of the twentieth century to account for the agency of the less privileged people in indigenous communities, suggesting that the less wealthy and well connected adopted Roman ways wherever possible (see Hingley 2005: 43).

Some authors have continued to use the term "Romanization" in a constructive way until the present, while others have critiqued and rejected both the term and the approaches that the theory embodies. For Roman Roth (2007: 10), Romanization is valuable as an "umbrella term" because it is "the most neutral term which can be used in this context—paradoxically—just because its original implications are so widely rejected." For Andrew Erskine (2010: 62), Romanization continues to be used "out of convenience rather than because it is considered to be especially useful. Nevertheless, it is a term that has proved very useful at provoking

useful debate." Neville Morley (2010: 110) writes that "'Romanization' is an ambiguous term that can be understood either as a policy or as a process—as the result of a deliberate attempt by the Romans at civilising their conquests, or as the unintended result of the incorporation of a region into the political, social, and economic structure of the Empire, or as some combination of the two".

Historical Background

Romanization in the Colonial World

Theodor Mommsen drew upon classical texts and epigraphic evidence from the Roman provinces to transform earlier approaches that had developed a rather binary and relatively static ideal in which barbarians became Romans through the adoption of the Latin language. Before Mommsen, no clearly defined idea of a Roman cultural package existed, and the idea that Latin culture could be adopted in a gradual, flexible, and transformative fashion was not very fully conceptualized. A transformative idea of Roman imperial culture was one of Mommsen's gifts to studies of the Roman Empire.

Haverfield helped to build upon this rather more dynamic account of Roman social change (Freeman 1997: 39, 42). In 1906, Haverfield adopted the term "Romanization" for the title and content matter of his influential article, "The Romanization of Roman Britain"; this publication was expanded in 1912 into a small book that was republished on several occasions. The use of this new concept helped Haverfield to consider the available textual and archaeological evidence for Roman Britain and to challenge the earlier approaches that had explored the influence of Rome on this province (Hingley 2008: 436). Mommsen and Haverfield's idea of Romanization drew the archaeological discoveries that had been amassed over the previous centuries into a study previously dominated by linguistic and literary conceptions (Freeman 1997).

Several factors came into play during the twentieth century that encouraged the development of this idea of progressive Roman cultural change. First, a new comprehension of the material culture of pre-Roman, Roman, and post-Roman people was being created – including houses, settlements, pottery, and metalwork – as the result of the increasingly systematic excavation of sites and the study of ancient objects. Alongside this process, there was a growing appreciation of the considerable depth of time that people had occupied Europe prior to the Roman conquest (Hingley 2008: 437). The accumulation of information about the material culture of Roman Britain gradually came to suggest that many artifacts and building types represented an amalgamation between the better-known Roman culture of the Mediterranean and the objects that were now recognized as having been used by the later prehistoric people of Britain. Second, a growing internationalization of knowledge led to the idea that there was a significant indigenous input into much of the Roman culture that was known from the provinces of the Western Empire, including many of the towns and villas. Third, the growth of ideas of social evolution during the nineteenth century, together with the increasingly problematic international political situation at the start of the twentieth, called for explanations of cultural change which emphasized that the conquest and control of indigenous peoples had, in the case of the Roman Empire, resulted in the transmission of civilization (Hingley 2005: 34–6).

New approaches to the cultural assimilation and incorporation of indigenous people in the Roman Empire appealed to archaeologists, ancient historians, educationalists, and politicians because they communicated relevant ideas in the imperial present. It is important that these accounts also drew directly upon some of the available classical texts (particularly Tacitus' *Agricola*: 21). In Haverfield's account, Romanization resulted in a fairly unified empire, since among the towns and upper classes of the empire, Romanization was felt to be substantially complete. Indeed, even the less wealthy rural peasants appeared to have been influenced by the example of Rome (see Hingley 2005: 35).

Comparable approaches to Romanization across the Mediterranean emphasized the incorporation of people into the Roman Empire, the

creation of effective imperial unity, and the elaboration of cities and gracious rural living (Hingley 2001: 76; Roth 2007: 11–3). Although the details of national discourses in the various Western European countries varied (see the papers in Hingley 2001), the accounts produced by Mommsen and Haverfield had a deep influence on the development of Roman archaeology across Europe. The focus of attention on Roman urban life and the upper classes was (presumably) inevitable at this time, since it represented the emphasis of the available classical texts and also the particular cultural fixation that had typified the interest of Western Europeans since the Renaissance. By focusing generations of work on the urban dwellers, the villa owners, and the Roman military, this research tradition helped to provide the archaeological evidence that was taken to support the ideas that had promoted the research in the first place. The idea of the highly Romanized landscape across the Western Empire was a colonial image, created by Rome and reproduced by modern scholars (cf. Hingley 2005: 92).

Approaches to the Romanization of provincial societies certainly did not create one entirely standardized international approach to classical archaeology, but there was a strong element of unity to the archaeological works that were published across Europe prior to the 1970s. This was posited on the idea that social change was relatively one sided and was promoted specifically by Rome for the benefit of subservient peoples in Italy and the provinces (Erskine 2010: 58–9). Changes in the political climate, however, were about to result in a sustained challenge to this received wisdom (Hingley 2005: 37).

Decentering Romanization

The decolonization movements of the middle decades of the twentieth century caused a wider intellectual challenge to the theories and methods that were used to study the Roman Empire. From the 1960s and 1970s, new types of archaeological materials started to be collected as the result both of the regional archaeological field surveys that were undertaken across Italy and the excavation of sites in Britain and the Netherlands as the result of development. The new focus on some rather less Roman-looking rural populations began to result in a changing emphasis of research that eventually led to the attacks that came to be mounted on the theory of Romanization (Hingley 2005: 36).

New accounts were developed that argued that monumental towns and villas were just one of the responses to the incorporation of rural societies into the Roman Empire, and the rural background to this urban-based civilization came to be more fully acknowledged. As a result, some Romanists began to challenge the dominant perspective, reflecting growing dissatisfaction with the colonial ways of thinking that in the West had dominated most areas of academia prior to the 1960s. The publication of Marcel Benabou's volume on African resistance to Rome in 1976 proved particularly influential, despite a frosty reception from some Romanists. Steve Dyson's article on revolt patterns in the Western Empire (1975) also led to a new focus of attention that aimed to combat the colonial knowledge inherent in earlier approaches. Direct attacks on the term "Romanization," however, took over a decade longer to develop, while some of these early attempts to redefine provincial identities were "nativist," in that they emphasized resistance to Rome through the active maintenance of indigenous identity in the context of imperial incorporation (Hingley 2005: 40–1).

One work that drew upon this nativist tradition to create a transformational perspective was Millett's*The Romanization of Britain* (1990). The value of Millett's perspective is that it emphasized an idea of Romanization that was of value to a postimperial generation. In order to achieve this, Millett stressed the indigenous input into the process of social change and identity formation in the Roman province but without losing a focus on the central imperial power of Rome. Romanization was far less of a direct policy that was implemented by the imperial center and far more the result of the efforts and desires of members of the indigenous elites that became caught up in the expanding empire. This argument had a deep impact since it enabled the creation of a less centralized and the less deterministic accounts of the Romanization of societies in Italy and across

the empire (e.g., Keay and Terrenato 2001; Roth 2007: 18–9). The idea of indigenous agency also impacted upon influential accounts of the Roman Empire that have consciously avoided the use of the term "Romanization."

Dismissing Romanization

During the second half of the 1990s, a number of British archaeologists turned critical attention to the concept of Romanization. In response, some Romanists argued that Romanization represented a value-free description of the process of Roman social change. For many Anglo-American commentators over the past fifteen years, however, the term "Romanization" is too problematic to continue to be of any value. Since the mid-1990s, a series of works have aimed to replace the term and the intellectual baggage on which it is based (e.g., Webster and Cooper 1996; Mattingly 1997; Hingley 2005; Mattingly 2006). Many British and American archaeologists and ancient historians have rejected Romanization, and some archaeologists in the Netherlands, Spain, and elsewhere have followed suit. The focus of many of these critiques is upon the political contexts in which the idea of Romanization became popular. During the late nineteenth and early twentieth centuries, this concept was popular, specifically, because it projected contemporary (modernist) concepts of progress and social evolution; in turn, such knowledge of the past can now be seen to have provided historical justification for ideas that were used to justify contemporary imperialism (Hingley 2005: 43–5). As Neville Morley (2010: 111) has argued,

> The superiority of Roman civilization, it was assumed, was such that it would then spread through the provinces by osmosis; it was enough for the natives to be brought into contact with Romans, whether soldiers, officials, colonists or traders, to recognize their superior status and wish to imitate them. . . . The close connection between these assumptions and the discourses of modern imperialism, which similarly see the colonized natives as uncultured or culture-free primitives in need of civilizing, is obvious.

The idea of the development of barbarians, or primitives, on the periphery of the Roman Empire to a more evolved and settled, Roman, condition of life matched contemporary interests and concerns for Britain and other Western nations that had empires or held imperial aspirations. In particular, Romanization propounded the positive value of the imposition of imperial order, downplaying the rights of indigenous societies to self-determination. This research tradition drew a direct but usually unacknowledged comparison between the character of imperialism in the ancient and the modern worlds.

These three stages in the development and abandonment of Romanization have been presented above as if they operated according to a simple and progressive logic in all of the regional and national traditions of study across Western Europe, but the fact that many Romanists continue to use Romanization theory today indicates that the situation documented here is not actually so simple.

Key Issues/Current Debates

As a result of the critical postcolonial dismissal of the value of the term "Romanization," many British and American authors have argued that we require new ways to view the process of identity formation and cultural change across the Roman Empire. It is necessary to define ideas that fit our current desire to live in a "postcolonial" world. A number of new approaches to identity and social change have emerged.

For some time, the influential interpretation developed by Greg Woolf (1998) in his research upon Roman Gaul appeared likely to grow to dominate the field. Woolf rejected Romanization as an approach and outlined the idea of "becoming Roman," exploring how the Roman Empire was characterized by "a new, highly differentiated social formation incorporating a new cultural logic and a new configuration of power" (quoted in Hingley 2005: 47). Woolf's account had a deep influence on Roman imperial archaeology, but a number of authors over the past decade have argued that "becoming Roman" adopts some of the more problematic aspects of Romanization, particularly in that it remains focused on the elite of the Roman Empire (Hingley 2005: 48). It

continues to emphasize the ways of life of the powerful and well connected and assumes that most of those involved in the Roman Empire had broadly similar aims and objectives. Carol van Driel-Murray has argued that the application of recent approaches to the Batavi of the lower Rhine Valley in the Roman period have created "undefined, undifferentiated and apparently entirely male" elites, and her critique can be extended to other recent approaches to individual societies of the empire (quoted in Hingley 2005: 91).

As a result, a body of work has developed over the past decade that aims to comprehend the local and perhaps rather fragmented identities that existed across the empire. Jane Webster's study of creolization (2001) has had a considerable impact, and some other works have focused on the identity of groups such as soldiers, traders, and industrialists; these accounts explore the variable ways in which these people were incorporated into empire (see works addressed in Hingley 2005: 91–116). Another influential approach has explored the discrepant experiences of the individuals who found themselves incorporated into the empire, addressing the highly variable nature of individuals and communities that were assimilated (Mattingly 1997). David Mattingly (2006, 2011) has developed this argument in detail in his informative study of Roman Britain as an imperial possession.

International Perspectives

It is unusual in Britain today for scholars to develop accounts that draw directly on Romanization, and when published works do draw upon this concept, a lengthy justification for the use of the term is usually felt to be appropriate. At the Roman Archaeology Conferences (RAC) and Theoretical Roman Archaeology Conferences (TRAC) in Britain and overseas, the term is usually used only in papers that seek to critique the research of past scholars. Romanization appears to have been abandoned by many who seek to study the Roman Empire. Despite the effective banning of the concept in certain circles, other authors – particularly those that address the Roman societies of Italy, Gaul, Germany, Iberia, and Dacia – continue to draw upon the concept of Romanization (for a survey, see Hingley 2005: 18). For instance, useful recent studies of Roman pottery and society in central Italy (Roth 2007) and society in Roman Dacia (Oltean 2007) adopt Romanization as an explanatory concept. The concept has been critically assessed by Germany scholars (Schörner 2005) and continues to influence the research of Roman cultural historians (cf. Wallace-Hadrill 2008: 103–4, 454).

In addition, recent reviews that address aspects of Roman imperial policy sometimes still champion the use of the concept, even if only as a result of the convenience of the term (Erskine 2010: 62). Many recent works that adopt the term evidently conceive that different societies could become Romanized in highly variable manners, ways that project individual cultural responses to their incorporation within the Roman Empire. Such studies take on board many of the critical points outlined by the authors who have sought to undermine the use of Romanization. Numerous others accounts of Romanization, however, remain more traditional in character, perpetuating earlier approaches without any particularly detailed justification. It has even been observed in discussion that the focus on abandoning Romanization is a British fixation, resulting from the United Kingdom's particular imperial history. This is an idea that appears to ignore the impact of classical ideas in national and imperial discourses in other parts of the world and also the role of Roman models in the political actions of the West today.

Those who remain critical of the use of the term continue to emphasize the way that it focuses research on the elite and the more Romanized peoples of the empire and also the way that it creates a rather simplistic interpretation of identity and social change (see Mattingly 2011). The investigation of the nature of the ways that the term has been used in different national traditions has hardly begun perhaps because the interrogation of the term often appears to be felt to be boring or irrelevant to current research on the people of the Roman Empire. A counterargument is that the study of research traditions needs to form a vital element in archaeological research,

since the materials that archaeologists address and the research traditions that the subject is based upon have been passed down though time, although they are also transformed through constructive and critical thought (Hingley Forthcoming). Indeed, Romanization should represent a lively area of international debate, but the two sides of the argument are rarely communicated in public discussion.

Future Directions

Currently, the field of Roman imperial archaeology does not have a single concept that serves to unite the study of provincial societies. Whether this lack of consensus represents a problem or an opportunity for Roman archaeologists is open to debate.

At a number of times in the past, particular works have served to focus academics research into agreed sets of approaches, theories, and methods. Mommsen's work had a deep impact across Europe, and this influenced Haverfield, resulting in a tradition of research on Romanization that dominated in Europe for the best part of a century. Martin Millett (1990) and Greg Woolf (1998) have added to this picture by creating powerful new ideas about Roman identity and cultural change that have considerably influenced subsequent studies. These works are useful for particular places and times, but none of these accounts provide an adequate picture of the nature and character of the transformative system that constituted Roman imperialism. Greg Woolf's theory of "becoming Roman" has had a lasting influence but continues, in the terms addressed here, to provide too focused an emphasis on the adoption of a Roman culture by the elite of Italy and the provinces. As a result, a number of other approaches have been developed that aim to decenter such concepts by exploring the variable ways that indigenous peoples were incorporated into the empire at different times and in various contexts.

Another approach that is being explored in current research is that of "globalizing Roman culture" (cf. Hingley 2005). Some Romanists are drawn to the analogy between the imperial Roman and the contemporary worlds precisely because this approach provides a means to appreciate the highly varied local responses to Rome without dismissing the idea of a central dynamic to imperial civilization. Richard Hingley has emphasized that a focus on the globalization of Roman culture helps to emphasize the current context in which knowledge of classical Rome is developing (Hingley 2005: 117–20). Past critiques of Romanization focus on the development of new approaches that are less closely tied to Western imperial discourses, but we need to continue to focus on the ways that ideas about classical Rome continue to be used to articulate the political and military actions of the West today (Hingley Forthcoming).

There appears, however, to be no consensus about how we might best approach the issues of Roman imperialism and cultural change, and this means that this field of study is open to a variety of competing approaches. Some archaeologists remain passionately supportive of the term "Romanization," and it is always possible that there will be a revival of interest in the Romanization of Britain in the near future. The concept has, however, been entirely abandoned by others.

Ippolito Rosellini

Malisony Lisa Grasso
Department of Historical Studies, School of Humanities, University of Turin, Turin, Italy

Basic Biographical Information

Niccola Francesco Ippolito Baldassarre Rosellini, better known as Ippolito Rosellini, was an Italian Egyptologist. He is considered the founder of Italian Egyptology. He was born in Pisa on the 13th of August 1800. His parents, Giovan Battista Rosellini and M. Angiola Biagetti, came from the city of Pescia in Tuscany.

Ippolito Rosellini started his studies at the University of Pisa when he was 17 years old. He mainly focused on Theology, Hebrew and Greek. He graduated in 1821, and he was then presented by Professor Bagnoli to the Grand Duke Ferdinand III as the best candidate for the Chair of Oriental Studies, shortly after being accepted to continue his studies in Bologna. Inspired and praised by Professor Giuseppe Mezzofanti, he published his first paper *La Fionda di Davide*.

After he completed his studies, he went back to Pisa in 1824, and he obtained the Chair of Oriental Literature and Hebrew. In the same year, he had the chance to read *Prècis du système hièroglyphique* by Jean-François Champollion, and he immediately became passionate about Egyptian studies. In August 1825 Ippolito Rosellini met Champollion in person; the scholar was in Italy to study Egyptian collections such as the one of Drovetti in Turin.

In 1826 Rosellini and Champollion met again; the Egyptologist went back to Italy to study the collection of Egyptian antiques of the British consul Henry Salt which was bought by the French government. The possibility of spending 4 months together in Livorno led to stronger mutual esteem and friendship; in fact Champollion considered Rosellini as his "loyal friend and disciple." Because of this special connection, Rosellini decided to follow Champollion on his travels and asked to leave the chair at the University of Pisa.

In the same year, the two scholars went to Rome, Naples, and Paris where they continued studying the collections of Salt and Drovetti for 7 months. In this period Rosellini met and married Zenobia, daughter of the Italian composer Luigi Cherubini.

While working together, Champollion and Rosellini started to plan to conduct an expedition to Egypt and Nubia. The French government was not keen on financing this enterprise, so Rosellini submitted the idea to the Grand Duke Leopoldo II. At the end he obtained the approval from both the Grand Duke and Charles X, King of France, together with the necessary funding in 1827. Rosellini was also nominated head of the expedition of the Tuscan group.

The expedition left Toulon on the 31st of July 1828, and it reached Alexandria on the 18th of August. Several areas from the Lower Egypt to Nubia were visited in order to study the main monuments and to copy the texts of numerous inscriptions. The travelers encountered difficulties, especially because of the extreme temperatures of the desert. The mission lasted over a year; Rosellini went back to Pisa in January 1830. As agreed, all the artifacts collected during the expedition were equally divided between France and the Grand Duchy of Tuscany; this is how the Egyptian collections of the Louvre Museum in Paris and the Egyptian Museum in Florence started.

A diary of the French-Tuscan expedition written by Ippolito Rosellini himself was published by Gabrieli in 1925.

In the summer of the year 1831, Rosellini went back to Paris to talk with Champollion about his intention to publish *Monumenti dell'Egitto e della Nubia* (See Rosellini 1832–1844), and the French scholar gave his consent. Unfortunately, Champollion died prematurely on the 5th of March 1832, and Rosellini had to carry on this project alone. Sadly it was also not possible for Rosellini to have the name of his friend on the publication due to the opposition of Champollion's brother who looked at the project with suspicion. Eight months later, Rosellini published the first volume of the *Monumenti Storici*, a publication rich of information that will count three parts for a total of nine volumes in 1841. A tenth volume will be added afterward by Niccolò Capurro in 1844.

During the years 1834–1835, Rosellini taught the first lessons of Egyptian and Coptic languages at the University of Pisa and through this became the founder of Italian Egyptology (See Rosellini 1937). He soon became well known, thanks to his teaching and his written work. His fame reached Richard Lepsius who went to Pisa to become his disciple and to perfect his studies in Egyptian antiquities in 1836. In that same year, Rosellini's health started to worsen after contracting a severe and incurable form of malaria fever during one of his trips to Egypt.

Ippolito Rosellini died on the 4th of June 1843 in Pisa when he was 42 years old. He was buried at the Camposanto Monumentale where other eminent scholars also rested in peace.

Major Accomplishments

Ippolito Rosellini's major accomplishments mainly originated from his extensive and profound dedication to Egyptology besides his interest for Hebrew language and Oriental studies in a broader sense. The collaboration with Jean-François Champollion was the most important stimulus for Rosellini, but during his studies, he had already proved to have the necessary qualities in order to become one of the most important pioneers of Egyptology in Italy.

Without doubt Rosellini's most remarkable achievement was the French-Tuscan expedition in Egypt, led side by side with Champollion in 1828–1829 (see Rosellini 1830). The expedition included people who drew the artifacts, botanists, architects, and workers. Their journey started in Alexandria and went through some of the most important destinations on the way to Nubia: Sais (San el-Hagar), Cairo, Menfi (Mit Rahina), Saqqara, Giza, Beni Hasan, Dendera, Tebe (Luxor), Esna, Edfu, Kôm Ombo, Philae, Abu Simbel, and Kalabsha. A large number of artifacts

were found, and it produced countless notes, drawings, and transcriptions. Unfortunately, numerous grave goods had to be torn apart in the intent of equally diving the findings between the two sponsors of the expedition. For example, the bas-relief of the pillar from the tomb of Seti I had to be divided in two parts (See Rosellini 1926); one part is now on display at the Egyptian Museum in Florence and the other is at the Louvre in Paris. Rosellini brought around 2000 artifacts back from the expedition in Egypt.

Once he came back from the expedition, Rosellini founded the first Chair of Egyptology in Italy, and on the same year, he started to work with his colleague and friend Champollion at *I monumenti dell'Egitto e della Nubia*. In 1830 he organized an exhibition at the *Accademia di Arti e Mestieri* of Santa Caterina in Firenze to show the Egyptian artifacts to the public. Rosellini continued his studies by publishing his project through over nine volumes; due to his poor health, he couldn't complete the revision of the tenth volume, the last. The tenth volume was published in 1844. From 1835 to 1843, he became director of the University library of Pisa and professor of Philology, Literature, and Eastern Archaeology.

After his death, his numerous books were donated to the library of the University of Pisa. In 1879, a few days after his death, his wife Zenobia Cherubini made the first donation following the instructions given by Rosellini himself. She donated other books in 1879, and their son, Giovan Battista Rosellini, made a last donation in 1879.

The donations include letters that show the richness of this scholar's intellectual networks, both in Italy and abroad (Fig. 1).

School of Archaeology and Anthropology, College of Arts and Social Sciences, Australian National University, Canberra, Australia

Basic Biographical Information

Andrée Jeanne Rosenfeld, B.Sc., Ph.D., FAHA (1934–2008) (Fig. 1), was an influential rock art archaeologist and scientist, who worked in Europe and Australia.

She arrived in Australia in 1972 as a well-respected young researcher and joint author of a seminal reevaluation of European Palaeolithic cave art (Ucko and Rosenfeld 1967). Her Ph.D. (Institute of Archaeology, University of London, 1960) under Frederick Zeuner on cave deposits from sites in Devon drew strongly on her science background (B.Sc. Physics, Bristol, 1956) and her interest in caving. Andrée continued her research combining the scientific, environmental, and human aspects of material culture and by 1964 was curating the British Museum Palaeolithic collections, researching European Palaeolithic cave art and assisting her then partner, Peter Ucko, teaching material culture at University College London.

Rosenfeld, Andrée, Fig. 1 Photo of Andrée Rosenfeld in 2001 taken by Tricia Edwards

She joined the Department of Prehistory and Anthropology, Australian National University, in 1973 where she remained until her retirement as Reader in 1997. She then moved to Southern Queensland where she built a home surrounded by friends; travelled, often to visit her family; became an accomplished weaver; and continued to write on rock art. Andrée died of pancreatic cancer in 2008.

Born in Belgium in 1934 into a brilliant academic family – both parents were well-qualified physicists – she was surrounded by European scholarship and languages despite experiencing the exigencies of a childhood overshadowed by World War 2. Her father, Professor Léon Rosenfeld, worked with Niels Bohr and Werner Heisenberg on the development of the Copenhagen Interpretation of quantum mechanics. Andrée's early family life underpinned her academic career and her combination of rigor and humanity.

Major Accomplishments

Palaeolithic Cave Art (Ucko and Rosenfeld 1967) was a small book of great importance. The authors questioned many existing theories about the interpretation and recording of European Palaeolithic cave art and provided a refreshingly open approach to an area of research still mired in superstition, old-fashioned techniques, and the understandable awe of early researchers such as the Abbé Breuil. In the 1960s Andrée worked at Arcy-sur-Curé with the leading French cave art researcher, Professor Leroi-Gourhan, who was using new, scientifically meticulous recording techniques and producing innovative interpretations of the associations between the animals depicted and the exact placement of the art within the cave system.

These research experiences, combined with her own precise scientific training, encouraged Rosenfeld to tackle new and innovative research in Australia. She arrived at a time when little fieldwork had been carried out in the vast field of Australian rock art. She led a team of colleagues and students to excavate and investigate the rock art of the Early Man shelter near Laura in Queensland – a milestone in the establishment of rock art research in Australia (Rosenfeld et al. 1981).

Andrée addressed the practical as well as the theoretical. She understood that conservation was imperative to the preservation and study of Australian rock art (Rosenfeld 1985). She understood that Aboriginal rock art embodied systems of social being beyond comprehension of symbols and figures. She was keen to make Australian rock art research available to a worldwide audience (Bahn and Rosenfeld 1991). By the late 1990s, she had became deeply interested in how rock art could be used in the understanding of the social contexts, which she demonstrated through her Central Australian field research (Rosenfeld 1997, 2002; Rosenfeld and Smith 2002). Her last paper (Rosenfeld 2005) was a bold analysis of the rich and complex relationship between the art and the song of the Arrernte people in Central Australia in recognition of the deep spirituality, knowledge, and culture that underlies all rock art.

Andrée established teaching courses at the Australian National University in the archaeology of art and the study of material culture and, with firmness and understanding, encouraged students, both at honors and postgraduate level, into active research. She received wide recognition through her election as Fellow of the Australian Academy of the Humanities. At her retirement, her students and colleagues, including Howard Morphy, Mike Morwood, Jo McDonald, Paul Taçon, Bruno David, Iain Davidson, June Ross, Ursula Frederick, and Nick Hall, produced a volume of papers showing the breadth and depth of her influence on the rapidly increasing area of Australian rock art research (Frederick et al. 1999).

Andrée's underlying strength was a rigorous academic discipline combined with creative and artistic flair. She was very self-disciplined and employed meticulous techniques in the field through to prompt publication. Andrée Rosenfeld was a pioneer in the field of Australian rock art, who demonstrated how the controlled application of scientific techniques combined with understanding and respect for indigenous communities would allow all Australians to appreciate the phenomenal richness and importance of Australian rock art.

Rostain, Stéphen

Stéphen Rostain
CNRS (French National Center for Scientific Research), UMR 8096 "Archaeology of the Americas", Paris, France
CNRS, Institut Français d'Études Andines, Quito, Ecuador

Basic Biographical Information

After his first contacts with New World archaeology in Teotihuacan, Mexico, and in the Maya site of Chaguite, Guatemala, Dr. Rostain focused his research on Amazonian lowlands and Caribbean islands. He was employed as an archaeologist in French Guiana from 1985 until he received his Ph. D. from the Pantheon-Sorbonne University in Paris in 1994. His dissertation was written on the archaeology of French Guiana.

Major Accomplishments

Stéphen Rostain is the first French archaeologist to dedicate his work to the Amazonian rain forest. He has developed innovative aerial archaeology along the Guiana coast, where he discovered thousands of pre-Columbian raised fields. From 1994 to 1996, he was the codirector of the archaeological project Tanki Flip in Aruba, which led to the publication of a large monograph. After the organization (with D. Schoepf) of the exhibition *Autoportraits du Nouveau Monde* in Geneva, Switzerland, he lived in Ecuador between 1996 and 2001, where he managed an archaeological project in the Upano Valley, particularly in the prestigious site of Sangay, famous for its numerous artificial earthen mounds. His main interests are historical ecology of the Amazon, pre-Columbian earthworks, indigenous agriculture, and ethnoarchaeology. One original characteristic of his projects is an interdisciplinary approach with an extensive team of specialists. He is presently Director of Research at the National Center for Scientific Research of France (CNRS) and between 2003 and 2011 has been in charge (the second one with D. McKey) of two interdisciplinary projects on the Guiana coast. Since 2012, he is conducting interdisciplinary project at the foothill of the Andes, in the Pastaza and Upano Valleys that were strongly impacted by ancient volcanic events. In 2008, he received the Paris Clio award for French projects in foreign countries. He was the director of the French Institute for Andean Studies (IFEA) in Ecuador between 2011 and 2013 and chairman of the third International Congress of Amazonian Archaeology in Quito, Ecuador, in 2013.

Routledge, Katherine Scoresby

Jo Anne Van Tilburg
Cotsen Institute of Archaeology at UCLA, Los Angeles, CA, USA

Basic Biographical Information

Katherine Scoresby Routledge (1866–1935) was born Katherine Maria Pease in Darlington, County Durham, England, the daughter of Gurney Pease (1839–1872) and Kate Wilson Pease (1840–1915). The second of five children and the eldest of two daughters, she grew up at Woodside, the Pease family home. Her paternal grandparents were Joseph Pease and Emma Gurney of Southend, Darlington. Joseph Pease, an industrialist, abolitionist, and pacifist, is known as the financial "father of English railways." All Pease and Gurney families were substantially wealthy and devout members of the Society of Friends (Quakers) for generations, and Joseph Pease was the first Quaker in English history to be elected as member of Parliament (Braithwaite 1857; The British Workman 1873; Pease 1992). Katherine's debut presentation to Queen Victoria took place in 1884.

In 1891 Katherine Pease was accepted at non-denominational Somerville Hall (now Somerville College), Oxford University. Gertrude Bell (1868–1926), a contemporary and Pease family friend, attended Lady Margaret Hall. Katherine was a serious student and strongly committed to women's rights. Her intellectual mentors included anthropologist R.R. Marett (1866–1943) and zoologist E.B. Poulton (1856–1943). She was acquainted with anthropologist Barbara Freire-Marreco (1879–1967). Katherine and only 11 other women (of her original class of 20) sat for exams in 1895, but none of them received anything above Honors 2nd Class. Nor were they granted degrees as a matter of policy. It was not until 1906 that Katherine and six other Somerville women claimed *ad eundem* degrees from Trinity College, Dublin (Fig. 1).

In 1906 Katherine married William Scoresby Routledge (1859–1939). Born in Melbourne, Australia, he was the son of William Routledge, a merchant, and Anne Sophia Twycross. Named after William Scoresby (1789–1857), an Arctic explorer, whaler, and natural scientist, William Scoresby Routledge's first cousin was John Milne (1850–1913), inventor of the seismograph. William Scoresby Routledge graduated from Christ Church, Oxford, and in 1882 he enrolled in University College London. In 1883 he

Routledge, Katherine Scoresby, Fig. 1 Katherine Maria Pease Routledge (left) and William Scoresby Routledge (right) ca. 1910. © Photograph Peter Bucknall. Easter Island Statue Project (EISP)/Van Tilburg Archives and Database

received the physiology prize and was elected to the Royal Geographical Society. In 1887 he received his M.A. degree from Oxford University, and in 1888–1889, he won the coveted Erichsen Prize for Practical Surgery. He departed Oxford without attaining his M.D. and travelled among the Micmac people in Canada. He departed there at an unknown date and journeyed to what was then British East Africa and is now Kenya, where he lived among the Kikuyu.

After their marriage at Darlington, the Routledges returned to Kenya, where they were entwined in a messy colonial scandal about which Katherine spoke out publicly. Referred to in the London Times as the Silberrad Affair, it involved sexual misconduct with minors in Nyeri, Kenya, by Mr. Hubert Silberrad, acting district commissioner. Katherine employed all of her political contacts to have the entire sordid affair brought before Parliament in open forum. It was noted that they were all "grateful to the lady for the action which she took" (Van Tilburg 2003: 67). In 1910 the Routledges published a co-authored, well-received scholarly work entitled *With a Prehistoric People: The Akikuyu of British East Africa* (Routledge and Routledge 1910). On March 28, 1914, the Routledges arrived at storied Easter Island (Rapa Nui) aboard their own yacht *Mana*, where Katherine spent 17 months conducting ethnographic fieldwork and, upon her return to England, produced her self-published, seminal work *The Mystery of Easter Island* (Routledge 1919). Other travels followed and then a major illness erupted. The Routledges parted under very trying circumstances. Katherine was diagnosed with "systemized delusional insanity" and was confined by her husband and family until her death at Ticehurst House, a mental institution in Sussex, in 1935.

Major Accomplishments

There is no question that the Mana Expedition to Easter Island, 1914–1915, co-led by William Scoresby Routledge and Katherine Routledge was the highlight of their marriage and the major achievement of their ambitious intellectual collaboration. They designed and built the yacht *Mana*, assembled a crew, and then sailed from Falmouth on March 25, 1913, bound for the Pacific and Easter Island. The expedition was fully funded by Katherine, who also assembled a scholarly advisory committee made up of experts in Western Pacific cultures and secured the necessary letters of introduction from the British Museum and other institutions. The voyage itself was a major accomplishment and a triumph over the direct threats of marauding warships during the opening stages of the Great War (World War I). In 1917 the Royal Cruising Club (founded in 1880) awarded the Challenge Cup "by special resolution of the Club to W. Scoresby Routledge for his cruise in the Pacific in 'Mana' and Exploration on Easter Island."

Once on Easter Island (now known as Rapa Nui), Katherine Routledge encountered an impoverished population of about 250 persons living in a repressive and exploitive colonial society. She was dismayed at the conditions people were living in and had at first little hope that she could answer the four basic research questions she and Scoresby had formed: Who were the original settlers of Easter Island? Where had they come from? What, exactly, did the hundreds of monolithic statues on the island mean? How are the statues linked to the present inhabitants? In fact, however, Katherine Routledge collected a massive quantity of unprecedented and irreplaceable ethnohistorical data including place names, family names, genealogies, and land ownership records. She conducted an archaeological survey of the 164 km^2 island that is still used today. Unfortunately, she and her team also conducted more than 30 excavations that are poorly documented. Nonetheless there is no doubt that her untiring devotion to interviewing Rapanui elders salvaged several generations of Rapanui prehistory (Routledge 1917; Van Tilburg 1996). Her observations of the environment, social behavior, the arts, land use, the economy, and customs remain a treasure trove of information to modern researchers. Housed today in the Royal Geographical Society (with the Institute of British Geographers), the British Museum, and the Pitt Rivers Museum, the Routledge papers and artifact collections are key to conserving the Rapa Nui past.

Royal Exhibition Building

David Tutchener
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

The Royal Exhibition Building is a unique feature of the built heritage of Melbourne, Australia. Governor Sir George Bowen laid the foundation stone on the 19th of February 1879 (*The Australian Sketcher* 1879), and the building was opened to the general public on 29th of May 1880. The Great Hall, the current building, is a permanent structure and is built of brick, while the basement and base are constructed of bluestone. Removable annexes that were used during the 1880 and 1888 World Exhibitions were constructed using wood and metal. The building itself was purposely built for the 1880 World Exhibition and was funded by the Parliament of Victoria (Official Record 1882). At the time of construction, the Royal Exhibition Building was the tallest building in Melbourne.

Image: Meyers, H.G. The Exhibition Building illuminated at night in 1901 to celebrate the federation of Australia. Museum Victoria: http://museumvictoria.com.au/reb/history/the-building/

The Royal Exhibition Building is recognized for its heritage value at state, national, and international levels. It is one of the only buildings that were constructed for the great exhibitions of the nineteenth century that are still used for their

original purpose. The Royal Exhibition Building held both the 1880 and 1888 World Exhibitions and showcased the relatively new colonial city of Melbourne to the world. In 2004, it was the first building in Australia that was recognized on the World Heritage List (Smith and Thomas 2014).

Key Issues/Current Debates/Future Directions/Examples

The 1880 and 1888 exhibitions played a significant role in the growth of Australia. The historical impact of the Royal Exhibition Building and associated Carlton Gardens marks Australia's growth from a collection of colonies to a nation. At the 1880 and 1888 exhibitions, the Royal Exhibition Building was divided into the exhibiting colonies and nations, which included many of the wealthy industrializing states of the time such as Japan, India, Russia, Germany, Victoria, Britain, the USA, New South Wales, Queensland, Tasmania, and many more. At the time of the exhibitions, Australia was still far from becoming a nation, but the spread of technological and cultural ideas through the exhibitions contributed to the development of the newly formed colonies that would later form the nation of Australia. The role the building played in hosting both the 1880 and the 1888 exhibitions was significant within the context of nineteenth-century world exhibitions and is the basis for the World Heritage listing of the building.

The architectural style of Royal Exhibition Building incorporates elements of Roman, Byzantine, Lombardic, and Greek Classical designs. This reflects the major influences in architecture throughout modern European development. In addition, the Royal Exhibition Building introduced to Melbourne an obscure style of architecture, *Rundbogenstil*, an early-nineteenth-century style that was made popular in Germany. *Rundbogenstil* makes use of a round-arched style and was well regarded due to its "rigidity of composition, repetition of identical elements and emphasis on direct structural expression" (Willington 1996: 53). With the assistance of ongoing maintenance and repair, the dome construction and cathedral-like influences have maintained their majestic nature over time.

Some 15,000 people attended the opening ceremony of the 1880 Exhibition on October 2, 1880, while over 24,100 people attended the Exhibition that day (Official Record 1882). The 1880 Exhibition saw an impressive total of 1.3 million people through its doors and captured the imagination of the colony and showcased over 32,000 exhibits from over 29 countries (Royal Exhibition Building Museum Project Volunteers 1996). At the time, The Royal Exhibition Building had what was considered the best view in Melbourne; a panoramic view for 50 miles was reported from the dome with the observation that a visitor could see the growing city at their feet. In all, the Exhibition took up an area of 22 acres.

The 1888 Exhibition opened on the 1st of August 1888 and closed on 31st of January 1890; it was considerably greater in scale and scope than its 1880 predecessor. The Exhibition's buildings covered 35 acres (United States Commissioners, 1890), and the Exhibition attracted over two million visitors, surpassing attendance at the 1880 Exhibition.

The 1888 Exhibition saw two major changes to the Royal Exhibition Building itself. The most exciting change was the introduction of electricity; over 825 brush arc lamps were added to light the building in order to extend its hours of operation. The other major change was a temporary "safety lift" or elevator that gave access to the roof and to a viewing platform. These advancements combined to display the prosperity of the colony of Victoria and its industrial advances.

The social and national significance of the Royal Exhibition Building is an outcome of the various uses of the building. In 1901, the Royal Exhibition Building hosted the opening of the first Australian Parliament, watched by a crowd of over 12,000 people. When the Duke of Cornwall and York stated "I now declare the Parliament of

the Commonwealth of Australia open" (The Argus 1901), the Duchess pressed an electric button that signaled outside the building for the Union Jack to be raised in all the state schools of the colony. The same parliament infamously saw the introduction of the White Australia Policy in an attempt to remove black laborers from the Queensland sugar industry (The Brisbane Courier 1901). The Countess of Hopetoun, who was the Governor of Victoria's wife, was also the first to raise the Australian flag at the Royal Exhibition Building on September 3, 1901.

The Royal Exhibition Building has served as a venue of national significance under the direction of the Australian Defence Force. In 1922 the Australian War Museum first opened in the eastern annex the Royal Exhibition Building. During the two and a half years that this museum was opened, it was visited by over 800,000 patrons (Dunstan 1996). The museum was a site of national mourning and outlined the First World War and the role of the Australian armed forces in this war. The museum displayed many objects that helped the audience to understand the everyday life of soldiers during the war, including gas masks, uniforms, and maps. The museum and its collection were moved to Canberra in 1935 (Willis 2004). The Australian Defence Force later used the buildings during the Second World War. The Royal Australian Air Force occupied the Royal Exhibition Building and the Carlton Gardens in 1940. At its peak, in 1942, the building accommodated over 2000 personnel. Conditions were tough, especially in the winter months. It was later used for low-cost accommodation for soldiers and sailors on leave in Melbourne.

Although not part of Australia's initial colonial history, the national significance of the Royal Exhibition Building and Carlton Gardens augmented its national significance during the post World War II period, when it was used as an emergency accommodation center for newly arrived immigrants and refugees from 1947 to 1962 (Lock 1996). The purpose of the accommodation was short-term housing for immigrants while they found work and more permanent housing. For most, the bungalows at the Royal Exhibition Building that housed families, couples, and single immigrants were their first accommodation in Australia. On the whole, the migrant reception center provided immediate and mostly adequate accommodation for the many poor and hopeful immigrants of the postwar period in Melbourne.

The Royal Exhibition Building and the Carlton Gardens have been utilized for numerous entertainment events including the 1956 Olympics and housing Australia's first aquarium. In between the two great exhibitions of the nineteenth century, on the 24th of February 1885, the aquarium at the Royal Exhibition Building opened. The aquarium housed animals such as crocodiles, seals, and penguins, and later after the construction of the fernery, this collection also included monkeys and birds. The aquarium was demolished after a large fire destroyed most of the structure in 1953. Across time the Royal Exhibition Building and Carlton Gardens have held a number of sporting events. Some of the more notable include the world's first 6-day penny-farthing race in 1882 and a scandalous tug of war competition in 1892 that included a women's event that was noted as being very improper at the time. Also the 1956, Melbourne Olympics held a number of events at the Royal Exhibition Building including fencing, weightlifting, wrestling, boxing, and the pentathlon.

The Royal Exhibition Building has been further etched in the memory of the Australian nation for its philanthropic utility. In 1930, during the depths of the great depression, Sidney Myer held a Christmas Day dinner. He was known for his generosity and fed 11,500 people from 10 am onward; they were fed corned beef and ham and were catered for in waves of 2000. Although the initial invitation to the dinner was for only 10,000 guests, an uninvited extra 1500 guests arrived and were welcomed. None were turned away (The Advertiser 1930). The Royal Exhibition Building has also acted as a hospital during the Spanish influenza outbreak in February 1919, which killed

over 3500 Victorians. The building was able to hold over 500 patients, but winter made heating the hall a problem, and patient transport was a major concern. The depth of public use of the Royal Exhibition Building and the Carlton Gardens marks out specific events in Melbourne and Australia's past and allows us to understand its unique cultural significance.

In 2012 the Melbourne Museum, the current custodian of the building, was given a 20 million dollar grant from the Australian Federal Government to restore the viewing platform at the base of the dome, which will afford a superb view of Melbourne. Museum Victoria director Patrick Greene said he considered it to be the "largest object in the museum's collection" (The Age May 2012) and there was also a possibility of extending a tunnel from the Museum to the building. These works are expected to be completed in 2019.

Ruffer, Marc Armand

Dario Piombino-Mascali
Faculty of Medicine, Institute of Biomedical Sciences, Vilnius University, Vilnius, Lithuania
University of Messina, Messina, Italy

SIR MARC ARMAND RUFFER

Basic Biographical Information

Born in Lyon on August 29, 1859, into an aristocratic family, Marc Armand Ruffer was the son of Baron Alphonse, a Swiss-born banker, and his German wife Caroline Prieger (Ventura 2017). Although his early education was in France and Germany, Marc Ruffer's professional studies were completed in England (Sandison 1967). He graduated from Brasenose College in Oxford (Arts) and from the University College of London (Medicine). He was also trained at the Pasteur Institute in Paris, under both Louis Pasteur and Ilya Mechnikov, and collaborated with the laboratory of Charles Bouchard at the Paris Faculty of Medicine (Cavaillon 2013). In 1891, the scientist was appointed first director of the British Institute of Preventive Medicine in London. Soon after, while working on diphtheria, he got infected and, as a consequence, suffered paralytic sequelae, which led to his resignation and his subsequent transfer to Egypt for convalescence (Sandison 1967). There, he settled in Ramleh (Alexandria), and, once recovered, became professor of bacteriology at the Cairo Medical School in 1896, as well as the president of the Sanitary, Maritime, and Quarantine Council in 1901.

While continuing his laboratory investigations, Marc Ruffer developed preventive medicine and undertook various public duties, including that of commissioner for the British Red Cross Society (British Medical Association 1917; Sandison 1967). For his services, he received a number of recognitions by the Ottoman Empire, Greece, Russia, and Italy, as well as a British knighthood in 1916 (Kelly's Directories 1916). He tragically died in the Aegean Sea on April 15, 1917, while returning from Thessaloniki, where he had traveled to improve sanitation of the provisional Greek government. His ship, the HMS Arcadian, was torpedoed by a German submarine, leading to as many as 277 casualties (Cavaillon 2013). Marc Armand Ruffer was survived by his wife Alice Greenfield, who he married in 1890. They had three daughters (Ventura 2017).

CHICAGO, ILLINOIS

Major Accomplishments

Beyond his accomplishments in the fields of immunology and hygiene (Swinton 1981; Cavaillon 2013), Marc Armand Ruffer is also recognized as one of the most prominent figures of modern paleopathology, in that he applied scientific methods to investigate archaeological human remains, identifying the wealth of medical information that could be extracted from them (Aufderheide and Rodríguez-Martín 1998). He began publishing his observations within this specialty as early as 1909 and continued until his death, with some of the articles being published posthumously. Although he was not the first to study mummified tissue histologically, Ruffer devised a successful method to rehydrate those hard, brittle, and friable specimens with a solution of alcohol and sodium bicarbonate, which led the way to the preparation of other similar fluids

(Sandison 1967; Aufderheide 2003). His most relevant finding was probably the diagnosis of schistosomiasis in ancient Egypt, extending back the history of this condition for millennia, of relevance for archaeoparasitology (Reinhard and Araújo 2008). Furthermore, he was able to find mummy evidence of anthracosis, pleural adhesions, kidney abscesses, and notably atherosclerosis, putting forward important views for understanding the natural history of this disease (Ruffer 1921). In addition, he hypothesized the presence of smallpox lesions on the skin of another Egyptian corpse, a theory that was recently challenged via genetic tests (Wertheim 2017). Among his other achievements was the diagnosis of tuberculosis in a subject showing Pott's disease, by demonstrating involvement of the psoas muscle in the infection process (Sandison 1967). Finally, he spotted baldness, blackheads, ulcers, and skin eruptions among the Royal mummies at the Cairo Museum through visual inspection (Ruffer 1921).

Beyond mummy science, Ruffer also contributed to bone paleopathology, with the description of several lesions including injuries, osteoarthritis, ossifying myositis, cancer, and tooth anomalies and disease such as wear, caries, abscesses, and periodontitis. He even reviewed the published literature concerning prehistoric trepanation and provided important observations on the diverse embalming methods (Ruffer 1921). On a different note, Ruffer contributed to the disciplines of medical history and iconodiagnostics, using literary and artistic sources to describe achondroplasia and other deformities such as talipes, Pott's disease, and rickets among the ancient Egyptians (Ruffer 1921). Accordingly, he reached the conclusion that consanguineous marriage among the New Kingdom and Ptolemaic rulers did not necessarily lead to ill-effects (Ruffer 1921). After his death, Lady Ruffer, who wished to accomplish the husband's desire to collect his archaeological contributions into a single book, encouraged publication of a monograph edited by anatomist Roy Moodie, the first comprehensive volume exclusively devoted to ancient disease (Ruffer 1921; Sandison 1967). In fact, it was Ruffer who popularized the term "paleopathology" in the scientific literature, providing its best definition in 1913 as "the science of the diseases which can be demonstrated in human and animal remains of ancient times" (Ruffer 1921: 139; Aufderheide and Rodríguez-Martín 1998). Despite this physician's tremendous contribution to the scientific analysis of mummies, however, the investigation of preserved human remains faltered after his demise, and paleopathologists returned to their interest in skeletal lesions until the mid-twentieth century (Aufderheide 2003; Aufderheide and Rodríguez-Martín 1998).

Rural Life in Islamic Archaeology

Stephen McPhillips
Department of Cross-Cultural and Regional Studies, University of Copenhagen, Copenhagen, Denmark

Introduction

The study of the rural world has become a significant area of growth in Islamic archaeology, and its potential as a source of data about past societies has been increasingly realized. As new approaches to the study of archaeological landscapes have become more common (Johnson 2006), features that would be missed in a more traditional focus on sites alone are now being documented by survey projects which investigate multiple strands of information in the extra-urban context. Archaeology visualizes and interprets human activity, often absent from historical accounts, which are primarily urban in their perspective and authorship. Where the countryside is cited in historical sources from the Islamic world, it is largely viewed as secondary or supportive to urban society. The material evidence, however, often points towards the important economic role which rural communities played. This is significant given that the economies of past Islamic societies were fundamentally agricultural in character and that the majority of the population is likely to have lived in rural areas. Material culture in this setting can include remains of agricultural and hydraulic infrastructure (such as field systems, canals, mills, terraces, and threshing floors) as well as settlements identified by the presence of standing architecture or by the visibility of surface artifacts or distinguishing features in soil or vegetation appearance.

In many rural regions of the Islamic world, less is understood about the traces of human activity from more recent historic periods than those of earlier times, an anomaly when contrasted with knowledge of historical landscapes in Europe, for example, where recent historic periods dominate survey data (Wilkinson 2003: 5). Prior to the mid-twentieth century, archaeological enquiry in much of the Middle East and North Africa focused on biblical or classical antiquity, while scholars of the Islamic past concentrated their attention on monumental architecture and fortified urban settings. Similarly, Islamic pottery studies tended to be centered on finewares, neglecting the establishment of excavated reference typologies and making it difficult to interpret material collected from rural sites, which is primarily composed of more utilitarian classes of ceramic object. Towards the end of the twentieth century, the focus shifted in many archaeological projects towards broader regional perspectives. Zones beyond major urban centers were examined in detail, and research questions began to address directly issues related to rural societies of the Islamic period. This has resulted in a combination of ethnographic and historical approaches and the incorporation of scientific methodologies, including remote sensing; geomorphological, archaeobotanical, and archaeozoological studies; and soil chemical analyses.

Definition

The rural Islamic world encompasses a diverse cross section of geographic, climate, and hydrological conditions, all characterized by agricultural activity as the principal means of subsistence. The inhabitants of this vast geographical area cannot be understood through the

Rural Life in Islamic Archaeology, Fig. 1 Open-air mosque, Qatar. (Image: Stephen McPhillips 2012)

perspective of singular ethnic, religious, or linguistic parameters. Similar circumspection is needed in developing models of how rural societies functioned, and the often cited dichotomy of the "desert and the sown" can sometimes be overplayed. Arid and semiarid environments are characteristic of many parts of the Islamic world, but rain-fed agriculture is also widely practised, and diverse landscapes zones (woodlands, marshes, high mountain, and upland plateaux and grassland) must be taken into consideration in a survey of rural life. Recent research has expanded knowledge of how agriculture was practised in arid zones that are no longer agriculturally productive. The reinterpretation of the role of so-called desert castles, or *qusur*, in the Syrian and Jordanian steppe is one such example of site hinterlands providing new interpretations of their function. Skillfully designed water procurement systems in fact permitted extensive agricultural activities, leading to long-term occupation, use, and reuse of many sites into the medieval or modern period (Genequand 2009).

Composed of diverse religious and ethnic elements, rural areas do exhibit characteristics that can be connected to the practice of Islam. This may include such features as cemeteries or individual burials which face the direction of the *qibla*, travel infrastructure linked to the *hajj*, or the remains of built or open-air mosques (Fig. 1). Further cultural commonalities can be detected in the material culture found in many rural contexts, such as the widespread use of lead and alkaline glazing on pottery vessels, or the morphological characteristics of the vessels themselves, such as the *ibriq*, or filter-necked spouted water jug, common in the Eastern Mediterranean after 1000 CE (Fig. 2). In the same region and further eastwards into Iraq and the Iranian plateau, the appearance of calcareous cream or buff fabrics in pottery assemblages in the eighth century has been noted in many archaeological assemblages, from substantially varied sites, and most likely produced in many different workshops. Their appearance has been interpreted as one indicator of a gradual shift in material culture from late antique Mediterranean traditions of red fine ceramic wares towards the fine cream vessels that were more prevalent in Iraq and are attested in particular at the major urban excavations of Raqqa and Samarra (Walmsley 2001).

Methodological Considerations

The discipline of Islamic archaeology has developed throughout the twentieth century in tandem with broader theoretical and methodological trends. Shared approaches with other disciplines (anthropology, biology, geography, geomorphology, and prehistory) have characterized some of the more recent large field survey projects. These

Rural Life in Islamic Archaeology, Fig. 2 Fired *ibriq*s at a potter's workshop, Lebanon. (Image: Stephen McPhillips 2012)

have given equal weight to remains from all periods of human presence in a given landscape, documenting long-term processes of landscape formation and change.

Even when settlements consist of standing architecture, taphonomic processes may obscure the archaeological evidence or blur chronological definitions. In western Syria, tell sites are readily apparent in the landscape, whereas low-lying dispersed settlements, which characterize occupation from the Hellenistic period onwards, are frequently located in open areas away from the earlier tell sites and have undergone intensive agricultural use (Philip et al. 2002: 19–20). In the Byzantine and early Islamic past agricultural lowlands in the Mediterranean also underwent periods of sedimentation and soil deflation (dependant on their location), linked to overly intensive farming practices and deforestation of upland zones (Vita-Finzi 1969; Casana 2008). Ethnographic analogies can be usefully applied when interpreting archaeological data across the Near East. Studies focusing on the rural Islamic environment can produce particularly fruitful results, when modern subsistence strategies are compared with archaeological data, partly because of their close temporal proximity. Pastoral, agropastoral, and sedentary agricultural modes of existence in the Middle Euphrates valley in the 1980s were analyzed in conjunction with archaeological and archaeobotanical data from extensive survey. A diachronic model was then proposed demonstrating how access to primary resources changed through time in direct relationship to settlement patterns and geopolitical factors. The significant investment in hydraulic and agricultural infrastructure that took place here from the seventh century is apparent in the revitalized Nahr Dawrin canal, built in the Neo-Assyrian period, but maintained and flourishing through the Umayyad and Abbasid periods, when the region alimented the large urban populations of the Tigris and Euphrates valleys (Berthier et al. 2001: 32–78, 165–168; Kennedy 2011) (Fig. 3).

New possibilities for interpreting survey and excavation data are being explored using remote sensing methodologies, which are now being applied systematically in archaeological projects. Archaeological evidence of occupation and settlement is often first identified through desk-based analyses, synthesizing many different sources of data, such as satellite imagery, maps, textual, or ethnographic sources. This can be verified by visits on the ground or walkover transects where access allows. The benefit of ground survey is that the collection of surface material may permit the detailed characterization of site function and suggest chronological attributes. More complex approaches to the assimilation of landscape data have been attempted using GIS where these

Rural Life in Islamic Archaeology, Fig. 3 Remains of the Nahr Dawrin canal, Syria. (Image: Stephen McPhillips 2009)

different data sources can be visualized simultaneously, providing an overview of rural land use. Criticism of this methodology when applied to Islamic periods includes its lack of sensitivity to the recognition of temporary, ephemeral, or seasonal habitation, and it is therefore unsurprising that evidence for these forms of occupation is underrepresented in the archaeological record.

Other challenges are encountered when using material culture to interpret rural settlement and occupation patterns. The tendency to assign ceramic wares to dynastic periodizations, based principally on urban sequences, can sometimes result in an oversimplified classification of rural pottery assemblages and consequently produce chronological models of regional settlement and land use which contain artificial breaks and lacunae. A recurrent problem is posed by the recognition of cooking pots and food preparation vessels, storage, and water transportation jars, typically made in local centers. They are challenging to distinguish from one district to another, although regional trends are often apparent. The problem is compounded for the early modern era, concerning which archaeological research, especially in the rural context, has only really begun in the last 20 years. Along with the development of reference ceramic typologies, a deeper analysis of vernacular architecture is potentially one route forward, with work currently being pursued in both of these directions. A further useful avenue involves collaborative research with historians who work with archival materials. Most areas that came under Ottoman control in the sixteenth century were documented in court records, tax registers, as well as *waqf* (endowment) records, and in many instances, these contain details of rural land holdings and resources. One caveat is that many of the chronicles, treatises, and encyclopedia of the pre-modern era are written exclusively from the perspective of a literate urban elite.

Historical Background

The earliest archaeological survey of Islamic-period remains was unsystematic, focusing on monumental architecture, and was often driven by the search for locations or civilizations associated with biblical or classical history. Scholars such as Smith and Robinson made extensive travels and recorded many observations about villages and landscapes in the Near East, recounting rural environments that are vastly different today (Smith and Robinson 1841).

Significant discoveries from Islamic periods were being made known to the western public in the early twentieth century, notably Musil's publication of the Umayyad bathhouse at Qusayr 'Amr in Jordan, while epigraphist van Berchem and the architectural historian Creswell systematically recorded Islamic monuments throughout the Middle East. The main focus of documentary work was on the fortifications and castles of the first Islamic frontiers or the crusades and counter-crusades of the twelfth and thirteenth centuries, while caravanserais linked to the hajj and postal networks saw detailed study in the Near East, Iran, and Central Asia.

Soviet archaeologists were active through much of the twentieth century in Central Asia, excavating at Islamic sites under the auspices of strongly centralized state institutions and within a Marxist theoretical framework. A notable feature of this work was the large "expeditions" and "complex expeditions," which analyzed many aspects of landscapes. For example, the South Turkmenistan Complex Expedition (YuTAKE) compiled extensive data about rural and desert environments, from the archaeological recording of architectural remains to ethnographic descriptions of twentieth-century populations and botanical, hydrological, and geological data. Tolstov's Khwarezmian Expedition also recorded multiple aspects of rural landscapes in the Amu Darya delta region of northwestern Uzbekistan. Rural Islamic society in this period was interpreted as essentially feudal, as in Tolstov's work at Kavat Kala, where a fortified citadel was interpreted as a center of power, and fortified dwellings in the surroundings as the estates of lesser landowners (for an overview, see Fedorov-Davydov 1983).

Large field surveys were also undertaken by expeditions in the Near East. Initially, the concern was the discovery of new archaeological sites in the light of historical sources, but this shifted towards a more holistic exploration of the hinterlands of urban centers. Islamic-period landscapes and sites were secondary foci for much of this work, but as early as the 1930s in the Balikh valley in the Syrian Jazirah, Mallowan combined historical sources and nineteenth-century traveller's accounts with survey results. He argued for periods of environmental prosperity and degradation, corresponding to tight control of rural resources under Abbasid rule, and of disengagement by the Ottomans (Mallowan 1946: 113). Adams' Diyala basin project in central Iraq, the "Lands behind Baghdad," dated the extensive canal networks and settlements he documented by association with ceramic surface finds and recorded all periods of human occupation discernible in this landscape. Referencing the stratigraphic ceramic sequence he established at the site of Tell Abu Sarifa, he extrapolated a peak in settlement numbers in the Sasanian period, tailing off in the ninth century. Adams' evidence corroborated textual sources for the intensive irrigation of the agricultural plain, supporting the establishment firstly of Veh-Ardashir, the new Sasanian capital, followed by the great Abbasid cities of Baghdad and Samarra. He argued that the diminution in size of the irrigated areas corresponded to the rise of the new Abbasid cities, reflecting a degradation that might be linked to over-exploitation of soils and overtaxation of its inhabitants and leading to a subsequent decline in their upkeep and in rural prosperity from the eleventh century (Adams 1965, 1970).

Field projects were now actively addressing Islamic periods as part of comprehensive landscape histories and new surveys undertaken from the 1980s in countries as diverse as the Morocco, Spain, the United Arab Emirates, Jordan, Syria, and Turkey looked directly at questions of settlements and land use in Islamic periods. The application of scientific survey and excavation methodologies, and the analysis of finds, has enabled Islamic archaeology to stand on its own merits, and subsequent work has revised a number of previously held assumptions. Until the mid-twentieth century, past Islamic societies were perceived by many western scholars in terms of social and economic decline. This is most strikingly apparent in the frequent interpretation of the geopolitical changes in the seventh century, the arrival of Islamic rule, as the collapse of a late antique order. Survey and excavation data was interpreted in these terms, and the extensive seventh century and later histories of late Roman and Byzantine village and agricultural life surviving in

the Levant and parts of North Africa went unrecognized or were ignored in the archaeological record. It was only as more careful attention was paid to archaeological evidence for Islamic periods, often involving the reinvestigation of previously excavated sites and the revision of ceramic typologies, that abundant evidence for social and economic continuity from late antiquity to at least the tenth century became apparent in many parts of the Mediterranean. Such revisions have accompanied a gradual shift in perception of the Islamic world from the 1970s, with Said's *Orientalism* raising awareness of the pitfalls of an unreflective western view of the Islamic world. The development of postcolonial archaeology has taken into consideration local and global discourses about the past in an attempt to avoid giving dominance to western academic perspective (Said 1978; Gosden 2012). The *Annales* approach to history also influenced archaeological studies of the rural world, concerned as it is with different timescales of change, notably the most gradual, unfolding over centuries (the *longue durée*). Resilience theory, offering a multidisciplinary perspective on human adaptation and reaction to ecological cycles of change, has recently been suggested as ideally suited to exploring the archaeology of the rural environment (Redman 2005; Walmsley 2007: 146–147).

Methodological advances in archaeology after the 1960s have permitted deeper analysis of arid or hyperarid areas of the Islamic world, where water procurement is critical. Site and regional survey in the basaltic Hawran uplands in southern Syria and northern Jordan demonstrate the value in reexamining landscapes once considered marginal, revealing successful management of seasonal and perennial water resources. A range of techniques were used for the storage and redistribution of ground- and rainwater, such as the sinking of wells along stream courses, the catchment and storage of rainwater, and the diversion of water into side channels and storage cisterns by means of check dams inserted across seasonal streams. The use of GIS to group data from many field projects reveals that the channels functioned over considerable distances, across a large area of the Hawran, and proved their sustained operation from the fourth millennium BCE to the early twentieth century CE. This hydraulic landscape seems most likely to have been maintained cooperatively at the local village level, rather than being more centrally organized (Braemer et al. 2009).

Geographical Range of Archaeological Work

Fieldwork investigating rural societies in Islamic periods has not been uniformly distributed, with Southeast Asia and West Africa only beginning to receive attention. The Iberian Peninsula has witnessed sustained growth in the study of Islamic archaeology after the reorganization of Spanish regions was completed in 1983. Studies of urban hinterlands and landscape surveys have since been undertaken in many areas (for an overview of key issues in Islamic archaeology in Spain and Portugal, see Boone 2009) (Fig. 4). Recent analyses of rural themes include the documentation of the development and modification of hydraulic networks under Islamic rule in Spain and the Balearic Islands (in particular see Kirchner 2009) and the recording of a large number of small fortified dwellings and agricultural estates located in rural areas (Bazzana et al. 1988). The study of material culture in the Vega plain, west of Granada, has more recently produced evidence of the complex processes of Islamic acculturation in the countryside (Carvajal 2013). In Portugal, work has demonstrated that while an expansion in rural settlement took place between the tenth and the twelfth centuries, an overall decline in the number of inhabitations may be linked to soil degradation (Boone and Worman 2007).

In North Africa, work during the twentieth century has focused on classical antiquity, but ethnographic studies of the rural world have also been well represented in Morocco and Algeria. Archaeological and historical studies of Islamic periods have begun to construct an overview of rural life across highly varied terrain, ascending from the coast to the high mountains and down into the fringes of the Sahara (for an overview, see De Meulemeester 2005). Elsewhere in North Africa, more limited attention has been given to the Islamic rural world. Surveys of the hinterlands of cities such as Carthage and Leptis Magna have

Rural Life in Islamic Archaeology, Fig. 4 Islamic-period terraced hillside, Ohanes, Almería, Spain. (Image: Ma. Teresa Bonet García & José María Martín Civantos)

demonstrated continuity of rural population well into the Islamic period (see Leone and Mattingly 2004 for a synthesis). In Egypt, the high density of settlement and land-use continuity in the limited cultivated space of the Nile valley and Delta has rendered survey difficult, while much information was lost when Islamic remains were cleared from pharaonic sites such as Medinet Habu without being studied. There has been less documentation of Islamic rural life in southeastern Europe, although recent surveys in Sicily, Crete, and Cyprus have brought forward knowledge of how rural communities related to imperial administration and regional economies. Work in Cyprus has looked beyond sites to seasonal settlements, hydraulic systems, monasteries, and agrarian remains of the Ottoman period in the Troodos mountains, interpreting the connections between settlement, agriculture, and landscape in relation to historical source materials (Given 2000).

The Levant and the Arabian Peninsula figure large in the archaeology of the Islamic rural sphere, and it is here that since the 1980s research projects have been designed with an explicit focus on understanding Islamic rural economy and society. Much progress has been made in constructing regional material culture chronologies, which enable the development of nuanced diachronic regional models of rural life in varied landscapes. Particular foci have been the Euphrates River basin in Turkey and Syria, prompted in part by large dam projects, and areas of western Jordan and Palestine where research resources have been concentrated for historic reasons. The excavations of Khirbat Faris, and the surveys of the Karak Plateau, and Hubras region of northern Jordan have enabled the investigators to characterize later medieval rural settlement, investigating how village economies functioned and changed through time (Miller 1991; McQuitty 2005; Walker et al. 2007). The Jordan valley and Palestinian coasts have seen the excavation and survey of many smaller sites, providing insight particularly into the sugarcane industry which flourished between the thirteenth and fifteenth centuries and revealing how rural populations were impacted by the Frankish occupation of the region. In the Arabian Peninsula, substantial development in the same period has driven much new archaeology in the Gulf countries, and questions of rural subsistence in semiarid zones, involving the analysis of irrigation systems, have been paramount in work undertaken on Islamic-period remains. In Yemen and Oman, life in coastal, upland, and desert regions requires a range of highly adaptive responses to varied climatic and hydrological

Rural Life in Islamic Archaeology, Fig. 5 *Qanat*s, Nishapur, Iran. (Image: © 2010 Google © 2010 GeoEye © 2010 Europa technologies)

conditions. Modern agricultural lifestyles continue to employ traditional techniques here, ranging from the use of terraced field systems at higher altitude to carefully managed oasis agriculture and irrigation networks in lowland and desert regions (Wilkinson 2003: 186–195).

In Iran and Central Asia, rural archaeological studies have been strongly divided between those areas practising rain-fed agriculture and those which rely upon the seasonal fluctuations of major river systems or artificial irrigation. Of the latter, the *qanat* systems of the Iranian plateau warrant particular mention (Fig. 5). Although in many cases it is difficult to attribute their establishment to the period after the coming of Islam, many of these systems were maintained throughout the medieval and early modern eras, into the present day. Historical case studies acknowledge the changeability of urban trends and the pressure this exerts on rural production (Bulliet 2009: 1–16). This relationship is also vividly portrayed in the archaeology of the oasis settlements of Central Asia, where intensive, highly structured cultivation of fertile river-fed lands enabled small rural micro-systems to evolve around major urban centers. The geography of Afghanistan presents an interesting challenge to rural models as the impassable mountains of the Hindu Kush brought forth altogether different approaches to agricultural production. Here, settlements nestled in the fertile valleys were as much dependent on the extreme continental seasonal variability as those in desert lands, giving rise to fluid and often mobile rural communities (Thomas 2008). Comprehensive studies such as that undertaken by Ball highlight the potential for analyses across this landscape of extremes, but recent political conditions mean that systematic ground survey is lacking, and more remote rural areas remain underrepresented and poorly understood (Ball 1982).

Key Issues/Current Debates

A range of issues of critical importance to the understanding of past societies has been raised by current archaeological research on the rural world of Islamic periods. The relationship between societies and the environment is

foremost, given the potential that study of the Islamic past has for incorporating historical and ethnographic data into archaeological studies. Evidence for environmental change in many areas of the Mediterranean has been detected from late antiquity well into the early Islamic period, with sedimentation of river valleys, soil degradation, and deforestation of upland areas part of a linked chain of processes influenced directly by agricultural and timber procurement practices. For later Islamic periods, isotope and pollen analyses have been used to construct models of colder more arid periods between 900 and 1150, and 1500 and 1650, both in the eastern Mediterranean and Central Asia, using a range of archaeological evidence. Such evidence feeds into broader discussion of social and cultural phenomena, linking rural life to geopolitical change and to ongoing global issues of climate change and sea and lake level fluctuation, as seen, for example, with the degradation of the Aral Sea in Central Asia (Sorrell et al. 2007).

The excavation of more rural sites, the establishment of solid regional material culture references, and the collection of more refined survey data in hitherto neglected regions now allow more subtle interpretations of settlement patterns and landscape use. Work at Khirbat Faris in Jordan has demonstrated that smaller rural sites could enjoy long-term stability based on agricultural activity, exhibiting evidence of integration with urban centers. Architectural units at Khirbat Faris were in use over many centuries, and the excavator suggests that seasonal or permanent occupation is likely to have continued after the sixteenth century, significant given the argument advanced by many scholars that settlement of rural areas of the Levant was then undergoing a major decline. Another current issue is the acculturation of rural populations. The careful analysis of material culture can reveal shifts in technical practices and stylistic choices through time, reflecting regional geopolitical developments. In Spain, this was manifest in changes in irrigation and ceramic technologies, while in the Levant the rural economy underwent a slow tilt away from being centered on a predominantly Mediterranean axis towards having stronger connections with Iraq. In northern Syria and Iraq, survey has corroborated textual evidence for investment in rural areas by the state, and the countryside saw the large-scale redevelopment of irrigation networks needed to support sizeable new urban foundations. Archaeobotanical (botanical, weed-flora, soil composition, pollen, and phytolith analyses) and zooarchaeological studies are at the core of a significant development in the study of Islamic rural life, the study of biological data. While Watson's thesis of an influx of new crops into the central Middle East alongside the arrival of Islam has not been corroborated by this research, many other indications of changes in agricultural regimes can be detected. An important botanical study in the Middle Euphrates valley suggests an importation of sophisticated new irrigation and agricultural regimes in the Umayyad period, continuing until the end of the fourteenth century. Characterized by both winter and summer planting seasons, a wide range of crops was grown in soils prone to degradation and salination (Watson 1983; Samuel 2001).

The rural Islamic world in the archaeological record is complex and changeable and should not be characterized in either positive or negative terms with regard to earlier or later societies. Nevertheless, as studies of archaeological and textual data progress, a picture of economic dynamism and close links to urban society both emerge as frequent themes. Centralized investment is apparent; irrigation development and land redistribution requiring massive investment in human resources and long-term upkeep were undertaken on the state level. Hydraulic technologies underwent major advances in the Islamic world, and in large parts of the former Ottoman Empire, in Iberia and Iran, agricultural products were processed using locally adapted water milling systems, often relying on limited seasonal water supplies (Fig. 6). Combined with the study of archival sources, studying the remains of rural technologies provides rich data about early modern economies. One new crop that has been significant in this regard is sugarcane, and significant evidence has emerged of the hydraulic organization, both in terms of water supply and milling operations, required behind its massive

Rural Life in Islamic Archaeology, Fig. 6 Al-Banjukiyya Watermill, Orontes river, Syria. (Image: Stephen McPhillips 2009)

cultivation in the microclimate of the Jordan valley (Kaptijn 2009). Hydraulic infrastructure and hydraulic energy use could be conceived and managed much more locally, calling to mind the example of the evidence from the Hawran. Artisanal production in the rural setting is one further related area of current archaeological enquiry. Ceramic, glass, and metalworking activities have all been documented at large scales in nonurban settings, indicating a perhaps surprising degree of integration between rural production and urban consumption. New evidence is emerging for expanded mining activities in areas as diverse as Portugal, Jordan, and Iran. As further methodological advances continue to be applied, it is hoped that geographic areas that are currently neglected by scholarship will be able to be examined, building a fuller picture of Islamic rural life. It is significant that the field is attracting new interest from scholars living in the countries concerned, often facing the enormous difficulty of preserving a disappearing rural archaeological heritage in the face of pressing modern economic realities. The destruction of remains is exacerbated when settlements and features are widely spread throughout the landscape, rather than in those areas where sites are highly concentrated. The collection of ethnographic data is now difficult in many parts of the world as traditional agricultural practices and rural traditions slowly disappear, but ways can be found to make this heritage relevant and beneficial to local populations. Initiatives in Wadi Dana in Jordan and at Ovakent in Turkey consider the economic needs of local communities by encouraging sustainable heritage tourism in projects conceived and run by specialists from the regions themselves, while the Turquoise Mountain Foundation seeks to foster traditional artisanal techniques in post-conflict rebuilding in Afghanistan (Coburn and Svensson 2010; Steen et al. 2010: 174–176; Bayizitlioglu 2012). Most landscapes of the Islamic past are living landscapes today, with active economic roles in their respective societies. For that reason, gaining access to the archaeological information they contain can be especially challenging, but the complex interplay between the past and the present is also a greatly rewarding field of enquiry.

Ruralia: The Jean-Marie Pesez Conferences on Medieval Rural Archaeology

Claudia Theune
Department of Prehistoric and Historical Archaeology, University of Vienna, Vienna, Austria

Basic Information

Ruralia is an international association for study of the archaeology of medieval and postmedieval settlement and rural life. The archaeology of rural life is an important issue, precisely because in medieval and early modern times, the majority of the population lived in rural settlements. The *Ruralia* association thus promotes research on such diverse topics including the nature of settlements, environment and landscape, economic systems (e.g., handicraft agriculture, the distribution of food), houses and other farm buildings, hierarchies, and other social dimensions. The temporal range of these covers the early medieval ages up to postmedieval times.

The association is an international European society registered as an association in the Netherlands. The first president of the association was Jean-Marie Pesez (1929–1998), and further presidents were Alan Aberg and Johnny de Meulemeester. At present 19 countries are represented: Austria, Belgium, Croatia, the Czech Republic, Denmark, Finland, France, Germany, the Grand Duchy of Luxembourg, Great Britain, Hungary, Ireland, Italy, Norway, Poland, Portugal, Russia, Slovakia, Spain, Sweden, and the Netherlands. Further countries are welcome to join the association. The coordinating body of *Ruralia* is the Ruralia Committee, which is made up from national representatives of all participating countries, led by the president (Claudia Theune, University of Vienna), a vice-president (Mark Gardiner, University of Lincoln), and an executive committee.

Major Impact

The association hosts biennial conferences across Europe in one of the participating countries. These provide a forum, especially for younger researchers, for presentation of new research and more general discussion of the full range of topics of interest to the association. The conference languages are English, French, and German. The first conference was held in 1995 in Prague (Czech Republic) followed by conferences in Spa, Belgium, 1997; Maynooth, Republic of Ireland, 1999; Bederkesa, Germany, 2001; Lyons, France, 2003; Dobogókö, Hungary, 2005; Cardiff, Great Britain, 2007; Lorca, Spain, 2009; Götzis, Austria, 2011; Smolenice, Slovakia, 2013; Clervaux, Grand Duchy of Luxembourg, 2015; and Kilkenny, Ireland 2017. The next conference will be held in Stirling, Scotland (September 2019). The conference papers are published as edited and peer-reviewed proceedings, of which 11 volumes are now available and listed on the association's website (www.ruralia.cz), where further information can also be found.

Russia: Management of Archaeological Heritage

Luidmila Valentinovna Lbova
Institute of Archaeology and Ethnography of SB RAS, Novosibirsk State University, Novosibirsk, Russia

Introduction

General Principles of Protection of Cultural Heritage in the Russian Federation

For Russia, the preservation of archaeological heritage means, firstly, the preservation of the 50,000 archaeological sites that are officially registered as archaeological heritage, and secondly, the preservation of an immeasurably larger number of archaeological sites that have not yet been put on record or remain undiscovered and so have not been scientifically described. Protection of archaeological heritage in Russia is of particular significance, because the period of recorded history in this part of Eurasia began much later than in many other areas of the Old World, and archaeological materials are thus the sole or main source for the reconstruction of historical processes until the Middle Ages, and in many parts of the country, until modern times.

The public authorities for cultural heritage protection are the Ministry of Culture of Russia and its regional offices in the administrations of the Russian Federation (committees, management, departments). The regional administration (committees, centers, inspection) carries out state control, registration, protection, and use of historical and cultural monuments in the administrations of the Russian Federation. In accordance with the legislation that underlies the whole system of protection of historical and cultural heritage in Russia, only identified archaeological sites assessed to be valuable historical and cultural sites, ensembles, or systems can be listed for cultural heritage protection by public authorities.

Russia has no single inventory of historical and cultural lands, including the diverse archaeological heritage, which is consistent with other codes (e.g., land, water, forestry).

However, more recently, a new factor in the destruction of archaeological heritage has quickly come to the fore. A wave of poaching has swept Russia, throwing on the shelves of antique stores thousands of rare finds. Illegal production of antiquities has become a well-established profitable trade, which involves hundreds of people. Also the European Convention on the Protection of the Archaeological Heritage was ratified by the Russian Government in June 2011.

Definition

Each national tradition in the field of cultural heritage has its own special terms. The basic terms and their definitions commonly used in Russia are discussed below.

Archaeological heritage is a kind of cultural heritage that includes settlements, burial mounds, the remains of ancient settlements, camps, fortifications and military camps, facilities, irrigation, paths, graves and places of worship, megaliths, rock art, sites of historical cultural layer of fifteenth to nineteenth century, ancient battle fields, and remnants of the ancient life of prehistoric people.

Objects of the archaeological heritage are a special type of real estate containing identified cultural heritage sites and are the exclusive property of the state. The objects of the archaeological heritage and land (or part of a water body, within which the object is located) in the legal turnover are separated.

Historical Background

Historical and Cultural Heritage as a Matter of State Regulation

Archaeological sites of Russia were first mentioned more than 300 years ago in connection with the development of Siberia when the Russian government began the search for ways to Eastern Asia. Thanks to a decree of Peter the Great in 1721, antiquities became a matter of national importance, and the foundations for research and scientific collections were laid. In the first months after the 1917 October Revolution, there was a series of historical events in the area of public policy with regard to historic heritage. Preservation of heritage was completely subordinated to the Ministry of Culture, and funding was provided by the residual principle, not nearly enough to solve the simplest problems. By the mid-1990s, there were signs of growing crisis in all spheres of Russian society, and there were radical changes in the field of heritage protection in general such as the development of state programs to protect cultural and archaeological heritage, including developing a series of legislative acts, a system of government protection and use of historical and cultural heritage, and the establishment and development of educational programs. Today, state protection of historical and cultural sites (including archaeological heritage) encompasses the legal, institutional, financial, information, and other measures taken by the state to identify, record, study, develop historical and cultural expertise, establish boundaries and territories of historical and cultural objects, and control their conservation and use.

Modern Legal Situation and Problem

Management of archaeological heritage in the territory of Russia is regulated by the RF Presidential Decree "On Particularly Valuable Objects of Cultural Heritage of Russian Federation Peoples" (1992) and RF laws "On Culture" (1992) and "On Objects of Cultural Heritage (Historical and Cultural Sites) of Nations of the Russian Federation" (2002). These regulations should form a legal basis for management of movable and immovable historical and cultural values. The RF Law "On Museums and Museum Funds" (2002) regulates management, restoration, and conservation of movable values; the RF Law "On Territories of Traditional Nature Management of the Minority Peoples and Other Ethnic Communities of the North, Siberia and the Far East" provides the legal foundations for setting up territories of traditional nature management, as

well as environmental, historical, and cultural heritage.

Archaeological works of different complexity should be conducted in conformity with the "Regulations on Open Lists" authorizing archaeological excavations.

These regulations should form a legal basis for management of movable and immovable historical and cultural values. However, in the judgment of many experts, the laws are incomplete and in need of subordinate legislation and adjustment in accordance with international legislation.

In the last few years, transformation of socioeconomic and political conditions of development of regions of Russia, especially Siberia and the Far East, raised additional problems concerning the protection of archaeological heritage. Socioeconomic problems, weak legislation, and an increasing crime rate have led to the growth of "black archaeology." In addition, numerous archaeological sites suffer from unfavorable ecological conditions and natural factors in zones of continental climate (e.g., wind erosion, floods, and mudflows).

Key Issues/Current Debates

Protection of Historical and Cultural Heritage in the Conduct of Business

The main challenge for Russian heritage managers is to expand their understanding of the term "object of cultural and historical heritage" to facilitate fundraising for the maintenance and restoration of numerous archaeological sites and to help integrate heritage management into the economic cycle. In Russia, we can now mark:

- Privatization of monuments (historical places, archaeological sites), imposing burdens on private property owners
- Development of cultural and tourism and the creation of heritage-based tourism products and brands
- Sales of the "aura" of historical and cultural heritage, when the attractiveness of historic districts is used to increase the value of new property

Therefore, if we talk about successful regeneration of heritage sites, as a rule, these methods are used in combination.

Historical and Cultural Examination

The first academic expeditions (1724, 1733–1743, 1768–1772) aimed at investigation of natural resources of Siberia were commissioned to "gather information about different rarities and antiquities." Researchers and explorers, members of the first Russian academic expeditions (D.G. Messerschmidt, F.I. Stralenberg, G.F. Mueller, P.S. Pallas, and others), and political exiles ("Decembrists" and members of the "Narodnaya Volya") collected rather extensive stocks of historical and ethnographical evidence. In the nineteenth century, research priorities were established for the departments of the Russian Geographical Society and, since the 1870s, the Russian Archaeological Society.

The existing system had several significant shortcomings. In particular, huge archaeological researches in the USSR were not provided with the proper degree of resources or personnel. At the same time, full archaeological mapping remained a matter for the distant future, and protection of archaeological heritage was a task of unimaginable scale. The only possible way out of this situation could be the ongoing development of existing and establishment of new regional centers.

Today more than 200 organizations are doing research in the study and conservation of archaeological heritage in Russia. The main research organizations are the Institute of Archaeology RAS, the Institute of Archaeology and Ethnography of SB RAS, the Institute of History of Material Culture RAS, and the Institute of Cultural and Natural Heritage.

Privatization and the Stewardship of Cultural Heritage

The 2002 Regulations of the Government of the Russian Federation allowed the privatization of historical and cultural heritage with the obligations of stewardship placed on the owner. According to Article 50 of Federal Law N73, objects not subject to privatization include

monuments and ensembles that are included in the UNESCO World Heritage List; especially valuable objects of cultural heritage of the Russian Federation, which are included in the state list of the most valuable objects of cultural heritage of the Russian Federation (the list No 1487 "On the most valuable objects of cultural heritage of the Russian Federation"); historical and cultural reserves; and sites of archaeological heritage. Thus, the archaeological heritage is completely excluded from commercial traffic and is the exclusive property of the Russian state.

Archaeological Heritage of Russia

The earliest evidence of archaeological cultures in Russia dates to the Lower Paleolithic. The material can be divided into major archaeological provinces, where different objects characterize different local areas – archaeological micro-districts. The main areas of concentration of Paleolithic sites are the territory of the Russian Plain, the Caucasus, the Sayan-Altai district, Transbaikalia, and Yakutia. Notable objects include Kapova Cave in the Urals, a complex of sites in the area Kostenki, Sungir and Avdeevo in Russian Plain, and Malta and Buret in Siberia are examples of Paleolithic art. Denisova Cave in the Altai Mountains represents an opportunity to observe continual development of human culture for more than 300,000 years. Mesolithic and Neolithic times are represented by short-term sites and large necropolises of 200–300 burials, indicating the development of cultures of hunters and gatherers in post-glacial era. A number of archaeological cultures have been identified – the Dnieper-Donets, Lyalovskaya, Kama and Volgokamskaya, Kitoyskaya, Syyalahskaya, Voznesenovskaya, and so on. The era of metal is a crucial time-related change in cultural and economic types, with an almost universal shift to producing forms of economy – agriculture and cattle breeding and development of metallurgical provinces. The archaeological culture of the Bronze Age – Early Iron Age – is associated with earlier ethnic entities. Groups include the Scythian-Siberian culture, Prebaltic and Baltic cultures, Finno-Ugric culture, Ural-Siberian culture, Huns, hunter-fishers of the East Siberian taiga, early Eskimos, the Okhotsk cultural and historical area, and the Far Eastern culture. Different levels of development have left us with unique pieces of ancient cultures, such as burial mounds (the largest includes Turbino, Pelenger, Sintashta, Andron, Karasuk, Koban, Pazaryk, and Tashnyk), fortified settlements (Archaim, Chicha, Ivolginsk), monumental art, and cave paintings. The Middle Ages – the time of formation of ancient states – produced the Turkic, Uygyrsky, Kyrgyz and Hazar kaganates, Kievan Rus, Volga Bulgaria, and the Mongol Golden Horde. In Russia, many of the cities are known for showing the development of crafts, architecture, temple construction, and building authorities. World-famous ancient Russian cities include Novgorod, Staraya Ryazan, Chernigov, and Pskov; cities on the Volga river in Bulgaria include Bilyar and Suvar; Mongolian cities and settlements include Saray, Tsarevsky, and Hadji-Tarhan.

Large-Scale Archaeological Rescue Work

In Russia, rescue archaeology has been undertaken for more than 80 years. In 1927, archaeologists began to study the archaeological sites in the flood zone of DneproGES (hydroelectric power station on Dnepr River). In 1929, the first expedition of GAIMK – Volga-Don was organized. In 1934, it was accepted by the Executive Committee and SNK that construction funds should be allocated to the excavation of archaeological sites to be destroyed by development. This made it possible to organize archaeological work in the construction of several power plants, the Volga-Don canal, as well as in the construction of the Moscow Metro. After World War II, rescue of archaeological work continued with the establishment of power stations on the Volga, the Yenisei, and the Angara and the development of the agricultural systems in southern Russia.

Today the development of the gas and oil industry, power complexes, and highways in Siberia and the Far East is of geopolitical importance for Russia. Transcontinental oil and gas pipelines, development of power complexes (e.g., Katun and Boguchan hydroelectric power stations), modernization of throughways and building new infrastructure, as well as a private housing "boom," require adjustment of legislation and

government control over the discovery and protection of cultural heritage, an increase in the number and quality of specialists involved in the assessment of threats, and monitoring and salvage of the objects of historical and cultural heritage located within development sites.

Public Organizations of Protection of Archaeological Heritage in Russia

At the present time in Russia, a number of different public organizations have emerged in connection with the formation of civil society. They have a significant impact on decision making in public bodies, including the protection of cultural heritage. The Archaeology Fund was established in 2004 as a noncommercial organization but has been actually functioning for almost 20 years. The establishment of the Archaeology Fund was a logical next step for ordinary people to help serve science.

The growing activity and importance of nongovernmental organizations involved in the protection of cultural and historical heritage of Siberia and the Far East is worth noting. The most effective are such organizations as the interregional movement "Siberian People's Council," the association "Cultural Tourism in South Siberia," the Federation of "Internet-Education," the Association of Culture Managers, and the funds "The Cultural Heritage of Siberia," "Society of Historical Archeology," and "ArcheoWorld." The main attention is paid to holding forums, festivals, and conferences, the development of cultural and scientific tourism, providing information about excavation, the organization of tours, and work with mass media.

Protection of Objects of Archaeology

Information support for management of cultural heritage, including discovery and inventory of archaeological heritage in the regions of Russia as well as for the development of schemes, cadastres, registers, and databases enabling consideration of historical and cultural potential of the territory, forms the basis for resource management in programs and projects concerning territorial objects or national parks, reserves, and protected territories.

The step beyond information support is to create museums for objects of archaeological heritage and to organize a series of archaeological parks. Today there are still only a few examples of museums at archaeological sites and of archaeological parks. Examples of archaeological parks include "Archaim" in the Chelyabinsk region, "Tomsk Pisanytza" in the Kemerovo region, "Crossroads of the Worlds" in the Altay region, and "Batakovo" on the Irtysh River. There are other famous projects, such as the "Archaeological Park in Moscow – Mitinsky Park," which includes 30 archaeological sites, and the "Park of Dolmens" on the lower River Jane (Krasnodars region, Couscous). The publicly organized "Taman" Archaeological Center has realized two projects, "Protection of Archaeological Memorials" and "Saving Ghermonassa Necropolis."

International Perspectives

UNESCO Activity in Russia

At present, about 50,000 archaeological objects of federal importance are registered in the territory of Russia. UNESCO World Heritage Sites in Russia make up 2.6% of the total, and only 12 archaeological sites are on the list of objects.

In the territory of Siberia and the Far East, a number of large-scale UNESCO and ICOMOS network projects in protection of historical and cultural heritage are currently under way. The most known are "UNESCO Associated Schools" (Omsk), "Museum Compass of Siberia" (Barnaul), "Dances of Nations of Siberia," and "Information for All."

Several large state universities (e.g., Moscow, Novosibirsk, Altai) have founded UNESCO international chairs to study problems in cultural heritage, archaeological and ecological education, and problems of the minority peoples of the north.

International Archaeological Heritage Preservation Projects in Russia

Russia supports intensive international contacts in the field of archaeological heritage, especially through scientific projects. In addition,

international cooperation in the protection of the archaeological heritage of Russia is implemented through a series of joint research projects, institutions of the Academy of Sciences, state universities, and individual research teams with colleagues from France, the USA, Canada, Germany, South Korea, Japan, and other countries. The largest international projects in cultural and scientific tourism which include Russian territories are "The Great Tea Road" and "China–Mongolia–Russia: Dialogue of Civilizations."

Future Directions

Information Resources in the Management of Historical and Cultural Heritage

Work on an inventory of historical and cultural sites in the territory of Russia is still in its developmental stage. Available resources can be divided into the following structural and thematic categories:

Information storage and retrieval systems, such as the "Museums of Russia" server, which contains links to the Internet sites of Russian museums and mobile exhibitions. Other systems include the catalogue of socioeconomic and humanitarian Web resources of the Irkutsk Interregional Institute of Social Sciences, which encompasses online catalogues of scientific and educational Web resources, the "Siberian Zaimka" and "SIBIRICA" data retrieval systems, and the museum portal "History and Culture of Siberian's and Far East Peoples."

Thematic Catalogues of Sites and Collections of Central Russia, Ural, Siberia, and North and Central Asia

Not all museums have electronic catalogues of archaeological collections as yet. We can get on summary information on collections in major museums – the State Historic Museum, Hermitage, Kunstkamera, Pushkin's Museum, and so on – which comprise several million archaeological artifacts. But there are some other sources, such as the catalogue of "Stone Sculptures of Altai" representing more than 300 sculptures of the Ancient Turkic Period, a virtual museum (digital collection) called "History and Culture of Nations of Northern Asia" which has a database and virtual museum of ethnographic collections of Siberian nations being created, catalogues of Novosibirsk State University's virtual museum "Ancient Art of Siberia," and the Information Center "Trade of War of Siberian and Central Asian Peoples."

Joint catalogues of regional museums of Russian cities, such as the "Catalogue of Rare and Valuable Museum Artifacts from Regional Museums of the Omsk's Oblast," the "Tomsk Regional Museum of Local Lore" presenting unique collections, and the "Archaeological Heritage of Karelia."

There is also the Web portal "Archaeology of the Russian Federation," the main objective of which is the preservation and maintenance of emerging Internet information in archaeology, history, ethnography, and related historical disciplines.

Popularization of Archaeological Heritage

Academic scientific organizations of the Russian Academy of Science possess rich archaeological, ethnographical, and paleontological collections, parts of which are exhibited at permanent expositions of the "Historical and Architectural Open-Air Museum" and the "Museum of Archaeology and Ethnography of Siberian Peoples." The catalogues of a few virtual museums have been created on the basis of these collections. Materials of some archaeological and ethnographic expeditions have been exhibited throughout Europe, in Asia, and also in Australia.

Features of Modern Legislation for the Protection, Utilization, and Conservation of Cultural Heritage

Local communities take measures to protect historical and cultural heritage, but these measures are restricted to territories of traditional land use or places inhabited by ethnic groups and sacral and clan territories. In our opinion, it is advisable to develop a complex of measures related to legislation, organization, information, and recreation

at the level of government regulation, through local government and in scientific and cultural communities, so the most important tasks are:

1. Information support for management of cultural heritage, including discovery and inventory of archaeological heritage in all regions of Russia as well as for the development of schemes, cadastres, registers, databases enabling consideration of the historical and cultural potential of the territory as a basis for resource management in programmers and projects aimed at territorial objects and/or national parks, reserves, protected territories, and so on.
2. Monitoring of cultural landscapes on macro level and at the level of individual objects of historical and cultural value. Studies of ethnic differentiation, traditional land use, and economic development of cultural complexes (in the context of the Durban Declaration).
3. Development of property aspects of historical and cultural heritage management on the level of territorial and local administration. Strong regulation of town planning and other forms of economic activity is needed.
4. Maintenance of a common information network of educational institutions, libraries, museums, and archives as a key component for improving the access to information and knowledge.
5. Development of practical strategies, technologies, and new models for enhancing the historical and cultural potential of territories with consideration of geopolitical, economic, scientific, and cultural factors.

S

Sabloff, Jeremy Arac

Robert W. Preucel
Department of Anthropology, Brown University, Providence, RI, USA

Basic Biographical Information

Jeremy Arac Sabloff is a leading anthropological archaeologist, specializing in the comparative study of cities and urbanism with a focus on the ancient Maya. His work is characterized by an intellectual commitment to balancing science and humanism. Born in 1944, he grew up in Manhattan. He received his B.A. from the University of Pennsylvania in 1964 and his Ph.D. from Harvard University in 1969 under the direction of Gordon R. Willey. He has taught at Harvard University, the University of Utah, the University of New Mexico (where he was chair of the department), the University of Pittsburgh (where he also was chair), and the University of Pennsylvania where he was Christopher H. Browne Distinguished Professor of Anthropology. At Penn, he also served as the Williams Director of the University of Pennsylvania Museum from 1994 to 2004 and Interim Director from 2006 to 2007. He is currently the president of the Santa Fe Institute in Santa Fe, New Mexico (Fig. 1).

Sabloff has held or currently holds many influential positions in the profession. He has served as president of the Society for American Archaeology, chair of the anthropology section of the American Association for the Advancement of Science, chair of the Smithsonian Science Commission, and editor of *American Antiquity*. He is a member of the National Advisory Board of the National Museum of Natural History and the Board of Trustees of the SRI Foundation and chairs the visiting committee for the Peabody Museum at Harvard University. He is the recipient of numerous professional awards and honors. Among the most prestigious of these are his memberships or fellowships in the National Academy of Sciences, the American Philosophical Society, the American Academy of Arts and Sciences, the Society of Antiquaries of London, and the American Association for the Advancement of Science.

Major Accomplishments

Sabloff is a specialist in Maya archaeology and has made major contributions to the understanding of settlement and urbanism. As a graduate student, from 1965 to 1968, he joined Gordon Willey's project at Seibal, Guatemala. His main focus was the study of ceramics. From 1972 to 1973, he and William Rathje developed the Harvard-Arizona Cozumel Project in Quintana Roo. In the course

Sabloff, Jeremy Arac, Fig. 1 Jeremy Arac Sabloff (InSight Foto Inc.)

of two field seasons, they studied approximately 30 sites in order to understand the role of long-distance trade in the development of Mesoamerican states. Although the project results did not support the port-of-trade model, the research provided an important new perspective on the Late Postclassic Period. From 1983 to 1988, he and Gair Tourtellot established a long-term project at the site of Sayil in Yucatan, Mexico. This project investigated for the first time the archaeology, environment, adaptation, organization, and history of an entire Maya city in the Puuc region of Yucatan.

Sabloff is equally well known for his contributions to the history of American archaeology. His overview of American archaeology, coauthored with Willey, was the first comprehensive history of the field. Significantly, they provided an intellectual genealogy for the rise of the new or processual archaeology by identifying four broad periods: Speculative (1492–1840), Classificatory-Descriptive (1840–1914), Classificatory-Historical (subdivided into Chronology (1914–1940) and Context and Function (1940–1960)), and the Explanatory (1960–present) (Willey and Sabloff 1974, 1980). Some of the important trends that they identified were the growing emphasis on evolutionary thinking, general systems theory, ecological models, and deductive reasoning in the context of making archaeology more scientific. They also argued that the new archaeology was not a revolution in the Kuhnian sense. Rather, it signaled a field in crisis yet to coalesce around a single theory. In their most recent edition (Willey and Sabloff 1993), they emphasize the importance of avoiding dogmatic thinking in method and theory and of acknowledging that the scientific and humanistic goals of the discipline are complementary rather than antithetical.

Sabloff has made numerous contributions to archaeological method and theory. He published with Willey an influential essay on the importance of history to processual explanation and argued that the Classic Lowland Maya collapse was due to an invasion of non-Maya peoples (Sabloff and Willey 1967). This essay was subsequently critiqued by Lewis Binford for not putting hypothesis testing first. In 1978, Sabloff joined the faculty of the University of New Mexico where Binford was teaching. At this time, he was focusing on the role of simulation in archaeology as a tool for understanding settlement change (Sabloff 1981). Team teaching with Binford led to an influential essay on paradigms and systematics that concluded with a plea for a "science of the archaeological record" (Binford and Sabloff 1982; Sabloff et al. 1987). Sabloff is committed to the comparative method to draw out insights about culture history and process. He coauthored a book on the rise of New and Old World civilizations with C. C. Lamberg-Karlovsky (Lamberg-Karlovsky and Sabloff 1979; also see Sabloff and Lamberg-Karlovsky 1975). A more recent

example is his book on ancient cities coedited with Joyce Marcus (Marcus and Sabloff 2008).

Finally, Sabloff is an outspoken advocate of the role of archaeology in the modern world and avid proponent of science communication. As the Williams Director of the Penn Museum, he eagerly embraced the challenges of educating the public about anthropology and archaeology. He published his book *Archaeology Matters* (Sabloff 2008) to demonstrate how archaeology contributes to the understanding and amelioration of present-day problems. Using his research on ancient Maya civilization as an example, he noted that the collapse of Classic Period Maya civilization provides important insights into such contemporary issues as overpopulation, shortsighted agricultural policies, and political competition. In 2010, he delivered the distinguished lecture at the American Anthropological Association's annual meeting, encouraging anthropologists to make their work accessible to their relevant publics and cultivate a new generation of scientist communicators (Sabloff 2011).

Sacred Site Conservation and Preservation

Georgios Alexopoulos
Initiative for Heritage Conservancy, Eleusis, Greece

Introduction

Sacred sites are widely considered to be different from other forms of archaeological sites and cultural heritage in that they represent and are imbued with sacred or spiritual values by a

religion, the adherents of a specific faith, or a group of people in the past or the present. In that respect, sacred sites are among the world's most popular visitor attractions (Shackley 2001) while religious heritage in general is estimated to constitute "perhaps the largest single category of heritage property to be found in most countries around the world" (Stovel 2005: 2). Because of their tangible and intangible associations and meanings and their potential active use for religious or other purposes, sacred sites demand particular attention, and their conservation and preservation often requires special treatment and sensitivity.

Definition

The popularity of sacred sites within the wider heritage industry can threaten their physical integrity, impose changes or impact their contemporary use. At the same time, the contemporary principles of conservation and cultural resource management, that demand preservation for present and future generations, can often advocate interventions and operational strategies that may seemingly compromise the very essence of a sacred site: its sacred or living heritage value and its use by traditional custodians or the people who value it. Therefore, when dealing with this specific type of heritage, archaeologists and other heritage professionals have great responsibility in recognizing both the human dimension of the site in question and the immaterial values it holds.

Key Issues/Current Debates/Future Directions/Examples

There is a very broad range of places that can be termed sacred sites and the differences relating to the geographical location, the antiquity, the size, the cultural and social affiliation, and other special characteristics may be enormous. One common way to categorize these numerous sacred sites is by distinguishing those that are today actively used by a living religious tradition or a group of people for religious or spiritual purposes (e.g., active churches, mosques, temples, monasteries, sites constituting or associated with pilgrimage destinations) as opposed to those that were valued for their sacredness or other intangible values in the past but are not religiously active in the present (e.g., the megalithic monuments of prehistoric Europe or the temples and sanctuaries of Ancient Greece and the Roman Empire). The latter share more similarities to historical monuments or sites with primarily archaeological value. However, in countries such as Greece, it has been argued that the importance of monuments that have served in building and consolidating national consciousness and identity, such as the Parthenon temple on the Acropolis hill in Athens, is subject to a certain form of sacralization (Hamilakis and Yalouri 1999). Even sites associated with long gone cultures or civilizations that archaeologists may consider "dead" can become a contested space and may be appropriated by groups of people that claim to continue old religious traditions, as witnessed in the case of the pagan/neo-shaman worshippers (Blain and Wallis 2007). It is also important to consider, when thinking of the spectrum of examples that the term sacred sites can encompass, that for certain cultures a sacred site may be a landscape thus emphasizing the role of the natural environment in this process – with Aboriginal Australian notions with regard to living landscapes a case in point (Colley 2002). In addition, there are also places such as holocaust sites, war memorials, burial grounds, or political shrines that are vested with certain holiness and religious undertones (Shackley 2001: 155–174). These places, although secular in character, can also be viewed as sacred by specific groups of people.

What becomes evident from the aforementioned range of examples is that, whether belonging to the major world religions or to the individual sacred traditions of indigenous people and descendant communities, dealing with sacred sites also means dealing with the people who value them. Without doubt, sacred sites have always posed certain challenges and problems to archaeologists and heritage professionals that have strived to conserve and preserve them. Indeed, approaches to the conservation of sacred

sites, in order to balance both tangible and intangible values, need to carefully consider issues related to different definitions of sacredness, ownership, right to worship, public access, and the wider meanings and associations placed by stakeholders on a local, regional, national, and international level. Active sacred sites that are valued as cultural heritage present additional complexities because they carry with them the requirements of contemporary life and cooperation among heritage professionals and religious communities can become particularly complex if the worldviews and consequently the aspirations and expectations towards any given intervention are different. Such examples truly demonstrate the difficulties in bridging modern secular standards of conservation and heritage management with traditional ways of life and faith.

It has been claimed that heritage professionals often find religion too hard to tackle because the religious context is too sensitive "to treat with objectivity and fairness" (Stovel 2005: 2) or because they lack the proper approach to understand it and to adequately articulate and communicate their aims to the concerned stakeholders (McNally 2011). The challenge, from the part of the conservator or archaeologist, is finding a way to conserve and preserve sacred sites without attempting to fossilize the traditions they represent and the religious groups that actively use them. On the other hand, custodians of sacred sites usually regard themselves predominantly as "facilitators of worship" and may have very different views on how the elusive spiritual quality of a sacred place may be preserved without serious compromises (Shackley 2001: xv–xvi). As a result, traditional ways of dealing with sacred sites do not often conform to conventional standards of heritage management practice. Furthermore, the way archaeologists and their institutions are perceived can hinder mutual trust and collaboration. For example, archaeologists are often not viewed in a positive light by indigenous communities because they are seen to intrude through excavation on sensitive sacred space and to provide interpretations that are sometimes not valid to local sacred beliefs (Layton 1989; Carmichael et al. 1994). Tensions and conflicts can arise particularly when heritage professionals are acting as an authority that dominates decision-making and excludes alternative voices. The case of the Orthodox monastic community of Mount Athos, a World Heritage Site located in Northern Greece, illustrates the difficulties of achieving mutual understanding and essential cooperation among the national archaeological authorities and the monastic authorities – the area being a self-governed part of the Greek state ruled by century-old customary traditions and laws (Alexopoulos 2010). In order to empower the Athonite monasteries in decision-making about the conservation and preservation of their own area, a special agency has been established (KEDAK = Centre for the Preservation of Athonite Heritage) with an administrative council that consists of representatives of several disciplines (e.g., archaeologists, architects, engineers), practitioners, academics, state officials (politicians), and, most importantly, members of the monastic community.

A very common source of tension and conflict between religious communities and heritage professionals is the adherence of the latter to principles and standards of practice that advocate the preservation of original material fabric and minimal intervention. When these principles dictate that a site should not be used for religious purposes and to accommodate worshippers, for example, for fear of physical degradation, they may clash with the worldview of a group of people that see preservation of continuity and use as primary objectives. In some cases, such as the active Buddhist temples of Sri Lanka (Wijesuriya 2005), authorities responsible for heritage conservation have taken into consideration the requests of the religious communities by offering alternative options to intervention without preventing contemporary use and the accommodation of religious practices. In a very different context, the conservation of ecclesiastical buildings in the United Kingdom has pursued to keep these places primarily in use for worship but often balancing preservation costs by also accepting an alternative or subsidiary purpose (Derrick 2004).

Some religious communities struggle to face the changes of the modern globalized world and

are resistant to its extensively secularized societies and the rapid modernization that is fueled by the advances of the information technology. At the same time, reconciling the potential of sacred sites as a financial resource with the widely held view that such places are a priceless public good (Shackley 2001: 80) is not always feasible. Many pilgrimage destinations – such as the sacred sites of the Holy Land for Christians, Mecca and Medina for Muslims, and the Char Dham circuit for Hindus – account for a massive movement of people and are supported by a large industry that is responsible for catering for transport, accommodation, etc. Consequently, another potential obstacle in the smooth cooperation between experts and nonexperts is the impact of mass tourism and the issue of visitor access on the nonmaterial qualities of sacred sites. Particularly challenging is to achieve a balance in relation to the common fear towards the perceived deconsecration of sacred heritage places by touristification or museumification (Alexopoulos 2010). When a sacred site becomes a tourist attraction, not all of the visitors can be expected to be adherents of the faith in question, but nonetheless, custodians and managers have the responsibility to accommodate accessibility, contemporary use, and any conservation interventions with respect towards the people who value the religious or spiritual values. Concerns over the carrying capacity of sacred sites in combination with a tendency to keep religious communities and worshippers uncontaminated by secular tourists often dictate measures for controlling and restricting visitor numbers, dress and behavior, and levels of accessibility (Shackley 2001). The visitor management strategies designed to cope with these problems, when formulated by the religious communities themselves, may often establish rules that exclude large sections of the wider public and limit the right of access to culture. The monasteries of Mount Athos, for example, ban female visitors from accessing the area and operate with a strict visitor quota that favors adherents of the Orthodox Christian faith. However, this measure, respected and not interfered with by-the-state heritage agencies, is deemed as vital for the raison d'être of the community of monasteries (Alexopoulos 2010).

The preservation of sacred cultural heritage has often also been jeopardized by conflicts among coexisting faiths. In the case of Jerusalem, a holy city for the monotheistic religions of Judaism, Christianity, and Islam, the challenge of preserving the several major religious sites existing within its Old City in a manner that supports tolerance and respect to all faiths can be difficult, particularly considering the tensions generated by current politics (Guinn 2006). In several other cases, religious monuments have been targeted for destruction on sectarian and ethnic grounds or as a consequence of religious fundamentalism as witnessed in the case of the Babri Masjid mosque in Ayodhya, India, or during the war that followed the breakdown of Yugoslavia and the creation of separate nation-states (Layton and Thomas 2001). Such deliberate destruction demonstrates the importance that sacred sites can have, as well as their subsequent vulnerability, as symbols of national or ethnic identity and as markers of multiculturalism and religious diversity.

Individual approaches to the treatment of sacred sites benefit from a consideration of archaeological practice and heritage conservation in a more global context. The trend towards recognizing the importance of sacred values attached to cultural heritage and dealing with the implications for the conservation and preservation of sacred sites can be traced in the postwar period. The original impetus for addressing relevant issues was provided by debates over architectural conservation, the desirable limits to restoration interventions, and the much disputed concept of authenticity. However, among the most influential developments underpinning the so-called values-based heritage management has been the Burra Charter (Australia ICOMOS Charter for Places of Cultural Significance), a policy document drafted in 1979 and revised considerably in 1999. This charter – and particularly its complementary guidelines (Australian Heritage Commission 2002) – constituted an important effort to address the notions of sacredness, spirituality, and continued traditional use by taking into consideration the associations, meanings, and heritage values of the indigenous Australian Aboriginal people.

Overall, the practice of archaeological heritage management in North America and Australia has paved the way towards an international heritage discourse that emphasized the recognition of indigenous heritage and has advocated the participation and engagement of a wider public in the conservation process. Within this context, the conservation and management of sacred sites has gradually featured in several specialized research programs and workshops of international organizations such as UNESCO (United Nations Educational, Scientific and Cultural Organization) and ICOMOS (International Council on Monuments and Sites). In recent years, ICCROM (International Centre for the Study of the Preservation and Restoration of Cultural Property) in particular has been actively promoting the conservation of living religious heritage by focusing on integrated approaches and community involvement. One of the most important developments, with potential future implications for sacred sites, is the special emphasis afforded to the notion of intangible heritage, as adopted by UNESCO's Convention for the Safeguarding of the Intangible Cultural Heritage (Ahmad 2006). Despite the criticism addressed towards the tendency to separate tangible and intangible heritage values, the convention itself has underlined the importance of various manifestations (e.g., oral traditions and expressions; performing arts; social practices, rituals, and festive events; knowledge and practices concerning nature and the universe; traditional craftsmanship) that resonate with many sacred sites.

To conclude, the conservation and preservation of sacred sites has never been an easy task for archaeologists and heritage professionals, especially when faced with the task to reconcile the standards and principles of contemporary practice (advocated by the experts) with the values and perceptions of religious communities and traditional custodians (the nonexperts). However, the tensions and conflicts often generated by different stakeholders over the preeminence of tangible or intangible heritage values can be overcome through tolerance, the development and fostering of mutual respect, the ability to formulate compromising solutions, and the recognition that conservation and sacredness can coexist. Archaeologists, in particular, can gain immensely from a better awareness of and a "more refined understanding of the workings and diversity of religious practices and beliefs" (McNally 2011: 172) (Fig. 1).

Sacred Site Conservation and Preservation, Fig. 1 A view of the Orthodox monastery of Iviron on Mount Athos, Greece – an important sacred site that constitutes a major pilgrimage destination, a World Heritage Site, and is host to a thriving self-governed monastic community with twenty ruling monasteries. Sacred Sites in Indigenous Archaeology

Ken Mulvaney
Rio Tinto, Dampier, WA, Australia
Centre for Rock Art Research + Management, University of Western Australia, Perth, WA, Australia

Brief Definition of the Topic

Australian indigenous sacred sites are both a place associated with customary practices and beliefs and a legal entity, identified and protected under Australian laws. It is a site in the landscape that is of specific cultural and social custom, a place of significance according to Aboriginal laws and traditions. Sacred sites are tied into the creation myths, song lines, personal histories, and events of the indigenous peoples. They connect individuals, both as traditional owners and custodians of the present with that of the Dreaming and map a totemic geography across the landscape, anchoring spiritual and kinship relationships to the land (see Elkin 1933; Berndt 1970; Strehlow 1971; Mountford 1976).

The Dreaming is a word to describe the creation time, its associated stories, and sacred sites, when the ancestor beings interacted with the land, created all living things, and formed natural features. Different Australian indigenous groups have their own word and understanding of this concept, like Tjukurrpa for the Arrernte of central Australia or the Pilbara Guruma word Yulurngulurngkamu. Indigenous Australian beliefs link the Dreaming, ancestor beings, sacred sites, and present-day actions into an integrated relational concept.

Sacred sites, although spiritually derived, have a physical manifestation, being natural features like rock outcrops, trees, water holes, or coral reefs or culturally marked places like stone arrangements and rock art. They can range in size and configuration from a single stone to a mountain range and embody both natural and culturally constructed markers. For indigenous Australians, the sacred is manifest in all aspects of nature and the landscape. Knowledge of sacred sites is learned through ritual attendance, initiation, and explanation of traditional law and lore. Singing the country and hearing and participating in the songs are ways of leaning about both the sacred sites and associated traditional knowledge. The act of singing and ritual renews and invigorates the spiritual essence of the land; it keeps the country alive (see Bradley 2010).

Protection of sacred sites is fundamental in ensuring the well-being of the country and people. Aspects of sacred sites may document historical happenings, inform on behavioral dictates and cultural values, and demonstrate personal links to ancestor, both Dreaming and genealogical. Places and knowledge may be restricted to gender, age, and initiation status. Locations and the mythological association of the place may be benevolent or contain great power which can destroy. Some places require the enactment of rituals and songs for the maintenance of species (see Daniel 1990). Other locations necessitate specific customary behavior to placate residing spirits or ensure illness does overcome the visitors.

The patterns of sacred sites weave a tapestry of resource access and control, land ownership, and traveling pathways. Areas and features are natural reference points throughout the landscape, many the physical manifestations of actions and marks created by the ancestor beings in the Dreaming. Some, like the Wandjina figures in the Kimberley rock art, are the shades of the Dreaming spirits (Crawford 1968; see also Lewis and Rose 1988). With these Wandjina figures, as with other sacred places, contain a dormant power that can be access through song and ritual performance.

The current social, educational, and traditional knowledge and land association of the indigenous people across Australia are variable, this often reflecting the timing, extent, and actions of white Australian occupation. Laws enacted for the protection and management of Australia's cultural heritage reflect this situation and what is important to the lawmakers. The *Northern Territory Aboriginal Sacred Sites Act* is undoubtedly the strongest in terms of protection and providing Aboriginal control in the process. Other states place more emphasis on archaeological rather than sacred sites, although, in cases, there are archaeological components to a sacred site. In the situation of the *Queensland Heritage Act 1992*, it specifically excludes places which would be regarded as sacred site but do not have material cultural evidence.

Sacred Traditions and "Art" in Hunter-Gatherer Contexts

Douglas H. MacDonald
Department of Anthropology, University of Montana, Missoula, MT, USA

Introduction

Prehistoric hunter-gatherers produced art and practiced sacred traditions, very often in tandem, leaving associated debris at archaeological sites across the world. This section of the encyclopedia provides a summary of aesthetics and sacred concepts in prehistoric hunter-gatherer contexts, as viewed from artifacts and archaeological sites. I define terms and provide a historical background, beginning with the origins of symbolism and language (Lieberman 1998) and progressing to the historical origins of hunter-gatherer art (Lewis-Williams 2002; Mithen 2006; Clottes 2008). I then provide a summary of key issues and current debates on prehistoric hunter-gatherer art studies, including method, theory, and interpretation, concluding with four international case studies. Finally, I identify several outstanding contributions to this field which provide further information for the interested reader.

Definition

Art is defined as the production of various modes of expression – music, paintings, sculpture, and literature – that influence human senses, emotions, and thought. Art is very often a reflection of sacred tradition, defined as the transcendence from the human realm to the spiritual one. All human cultures have a conception of what is sacred to their world, usually encompassing beliefs in their origins, morals, and reasons for existence (Bellah 2011). Some anthropologists have proposed that the capacity for religion and sacred belief is an evolved characteristic of the human mind, an adaptive strategy for survival (Mithen 1996; Lewis-Williams 2002).

Art is often used to express such beliefs, but should not be thought to exclusively reflect that spiritual realm (Whitley 2011). Just as humans in the current age, hunter-gatherers in prehistory used art to express a much wider variety of experiences beyond the sacred, including subsistence practices (hunting, gathering, fishing, etc.), various material aspects of their world (animals, people, plants, etc.), historical events (battles, hunting scenes, etc.), and social life (dancing, ritual, etc.). While anthropologists have established the complex nature of both music and literature in contemporary hunter-gatherer society (Patel 2007), no material remains – in the form of sound recordings or books – exist for these forms of art in archaeological contexts. Archaeologists attempt to understand prehistoric music by the study of the few musical instrument artifacts found at archaeological sites (Mithen 2006), while literature study is restricted to the interpretation of rock art panels to gain insight into myths and stories of prehistoric hunter-gatherers.

As such, without music and literature, archaeologists are left to study art of prehistoric hunter-gatherers through objects, paintings, and sculpture found at archaeological sites. Namely, archaeologists study two types of artifacts: (1) art material culture (manufactured objects, sculptures, or portable objects) and (2) rock art (also referred to as parietal art). Art material culture is found as various forms of sculpture, using a variety of mediums, including ceramics, rock modification, plants (e.g., twig figurines), and other physical objects (Fig. 1). For example, this small palm-sized river cobble found at Ghost Cave in Montana was transformed into a human face effigy; it is a good example of art material culture, or portable art. Rock art is identified at archaeological sites in the form of pictographs, or

painted images (Fig. 2), and petroglyphs, or pecked images (Fig. 3) on rockshelters, cliff faces, large boulders, and other similar lithic landscapes. Using these two types of art, archaeologists study hunter-gatherer aesthetics in the past. This image shows a human (anthropomorph) and associated animal pictographs painted in red ocher on a cliff face in central Montana, while this petroglyph shows etched human figures engaged in a gun fight on a rock wall in southern Alberta, Canada.

Sacred Traditions and "Art" in Hunter-Gatherer Contexts, Fig. 1 Human face effigy recovered at Ghost Cave, Montana, United States. (Courtesy Montana Fish, Wildlife, and Parks)

Archaeologists often study art to understand the second topic of this encyclopedia entry, sacred tradition. Art often is produced for, or is at least inspired by, human beliefs in the sacred (Lewis-Williams 2002). For archaeologists who study hunter-gatherers, art is the only means by which we can study ancient religion and spiritual beliefs. Hunter-gatherers, because of the mobile nature of their world, generally did not produce religious architecture, such as kivas used by the Anasazi (see "▶ Chaco Canyon, Archaeology of," this volume). Hunter-gatherers also did not leave behind literature and music, as discussed above, although they surely had myths, stories, and music about these important aspects of their lives (Mithen 2006).

Thus, for purposes of this entry, sacred tradition is reflected in archaeological sites only through art material culture and rock art. For example, Fig. 4 below of a Dinwoody figure in Wyoming is thought by archaeologists to reflect Shoshone Native American vision quest practices, an important aspect of their sacred traditions.

Sacred Traditions and "Art" in Hunter-Gatherer Contexts, Fig. 2 24JF695 Foothills-Abstract rock art showing a human and turtle painted in *red ochre*, Montana, United States. (Courtesy of Mavis and John Greer)

Sacred Traditions and "Art" in Hunter-Gatherer Contexts, Fig. 4 Dinwoody rock art, Legend Rock, Wyoming, United States

Based on ethnographic studies of Shoshone Native Americans, Francis and Loendorf (2002: 110) explain that, "Engravings and paintings were created the morning after a vision was received in order to preserve it, as forgetting the details of the vision could result in death or illness." Hunter-gatherers, thus, often represented their sacred traditions in art, either as portable objects, non-portable sculptures, or rock art, that archaeologists can study to understand human prehistory.

Historical Background

Archaeological sites throughout the world are filled with an enormous wealth of information regarding sacred traditions and art used by hunter-gatherers in prehistory. For at least 100,000 years, people have produced art as a means of social interaction, to form alliances, to establish territories, to express themselves, to practice their religions, and to broadcast important

information (Bahn and Vertut 1997; Lewis-Williams 2002; Clottes 2008; Fagan 2010). While subsistence, economy, technology, and settlement systems are thought of as the key points of study for hunter-gatherer archaeology (see "▶ Hunter-Gatherers, Archaeology of" and "▶ Hunter-Gatherer Settlement and Mobility," this volume), the study of aesthetics and religious beliefs is also important. Due in part to the comparatively large size and organizational complexity of our brains, humans are alone in the animal kingdom in having evolved the capacity for complex thought (Mithen 1996). With this complex thought, humans evolved the origins of symbolism – the representation of one thing as another – which has also led us to a capacity for three additional uniquely human innovations: (1) language, (2) beliefs in the sacred, and (3) aesthetics (art). As Philip Lieberman (1998: xiii–xiv) states in his study of the evolution of human language, "horses run faster, gorillas are stronger, bacteria adapt faster to different environments. Speech, language, and thought differentiate humans from other species."

The prehistory of early art has long been controversial and, thus, is a fairly well-studied topic. Lewis-Williams (2002), among others (Whitley 2011), provides excellent overviews of the history of study of hunter-gatherer art. Among the early scholars instrumental in the study of prehistoric hunter-gatherer art include the Abbe Henri Breuil. Breuil's studies of early cave sites such as Altamira in Spain were critical in establishing the antiquity of art into the Upper Paleolithic period. Since then, numerous archaeologists have studied prehistoric hunter-gatherer art, including Andre Leroi-Gourhan and Champion (1982), Paul Bahn and Jean Vertut (1997), and Jean Clottes (2008) in Europe; David Lewis-Williams (2002) in South Africa; David Whitley (2011) and Keyser and Klassen (2001) in North America; and Ronald Berndt (Berndt et al. 1992) and Geoffrey Bardon (Bardon and Bardon 2004) in Australia.

One of the main foci of study of these hunter-gatherer art researchers is the origins of early art in their respective regions of study. Bahn and Vertut (1997) provide a summary of the origins of art that place the production of art material culture (art objects) back to more than 100,000 years ago in both Africa and Europe. Such art consists of ornamental jewelry, including incised bones and other human-modified natural objects (e.g., shells with bored holes) presumed to have been used in decoration/jewelry. In 2011, Henshilwood and colleagues reported in the journal *Science* on a 100,000-year-old red ochre-processing site – Blombos Cave – in South Africa which is the earliest evidence for the sophisticated and organized production of material used in modern human art production (likely used in the painting of objects, rock art, or bodies). Also in 2011 in *Science*, Henshilwood and his colleagues also recorded the earliest production of ornamentation – a string of perforated shell beads – at the same site, dating back to some 77,000 years ago. Finally, in 2002, these same archaeologists recovered a polished red ochre fragment with a motif of three parallel lines and patterned crosshatches that date to approximately 75,000 years ago (Clottes 2008).

Whether ornamental objects and incised rocks, such as those recovered at Blombos Cave, should be considered art is a key research question in dispute by archaeologists and art historians alike; without question, ornamental objects and incised or etched objects represent the earliest examples of human symbolic capacity associated with the origins of the uniquely human mind (Mithen 1996). Along with this, some also propose that this period – c. 100,000 years ago – likely marks the origins of human language, a similarly symbolic, uniquely human invention (Lieberman 1998).

Today, archaeological evidence for the earliest human art – that goes beyond ornamentation and incised tablets – is found at archaeological sites in Eurasia and Africa dating to approximately 30–40,000 uncalibrated years ago (Bahn and Vertut 1997). This marks the important event known as the Middle to Upper Paleolithic transition in which modern humans emerged in the Old World and migrated out of Africa into Europe, Asia, and Australia. With those major migrations, humans transported their art and sacred traditions, transforming them within

their new environments, wherever they decided to settle down and make their home.

In Africa, we commented above on the important work of Henshilwood and his colleagues at Blombos Cave, South Africa, pushing the origins of symbolic thought and art-like objects back to between 75 and 100,000 years ago. The earliest well-dated art objects (not ornamentation) in Africa are from Apollo 11 Cave in Namibia and include several animal figures painted on stone plaques that date to approximately 26,000 years ago (Lewis-Williams 1984: 230).

In Europe, art objects and parietal art date to approximately 30–35,000 years ago, with the earliest being a group of 17 ivory figurines from three caves in Germany; one of these from Hohlenstein-Stadel depicts a transformative figure of a human with a lion's head (Mithen 1996). The earliest painted parietal art in Europe is from Grotte Chauvet in France, at 32,000 years ago. Discovered in 1994, Grotte Chauvet remains the earliest well-dated European rock art site and is the oldest painted cave in the world (Clottes 2008). Its sophistication is unparalleled in Upper Paleolithic rock art; as such, it is assumed by most archaeologists and art historians that art was produced prior to this time but remains undiscovered at Old World archaeological sites.

While Europe has been the major focus of early rock art researchers, Bahn and Vertut (1997: 31–34) provide a summary of the earliest indisputable art in other regions of the world. In Asia, an archaeological site in Shanxi province, China, yielded a perforated stone ornamental disc dated to c. 28,000 years ago. Australia's earliest art sites include Koonalda Cave which contains human-produced striations in the cave walls that are dated to between 15 and 30,000 years ago. Finally, in the Americas, early rock art has been identified in Texas at the Gault Site, with incised bone objects dating to greater than 11,000 uncalibrated years ago. Overall, the earliest examples of art are of a similar age to the first presence of modern humans in those regions, implicating art as a uniquely human endeavor that was carried with humans as they migrated across the continents.

Key Issues/Current Debates

What Is Art?

In addition to studying the history and origins of hunter-gatherer art, the definition of art is another research issue for prehistorians. Some believe that ornamental objects such as those from Blombos Cave should be considered evidence of true art, while still others believe that the definition should be restricted to actual art material culture (portable art), sculpture, and/or paintings, as we have defined here. We leave that debate open for future archaeologists of hunter-gatherers to resolve (see Mithen 1996: 154–163).

Dating of Art

The dating of art is another major focus of archaeologists interested in the study of hunter-gatherer aesthetic and sacred traditions (Keyser and Klassen 2001; Whitley 2011). Dating art can often be quite difficult, but recent methodological advances in dating methods are allowing us to date art in innovative ways. Art of hunter-gatherers can be dated by four main methods: (1) association with dated archaeological sites or objects, (2) datable subject matter, (3) superimposition of designs, and (4) chronometric dates on the art itself. The first method – association with dated archaeological sites or objects – associates the age of an art object to a well-dated archaeological deposit from the site of the art itself or an associated one.

Second, the subject matter of the art might give its age away. In the Late Pleistocene, mammoths and mastodons and other now-extinct animals are pictured in art; we know that these animals went extinct at the end of the last ice age, so therefore we also know that any depiction of these animals predates the end of the ice age, c. 11,000 years ago. In the Americas, the depiction of the horse in Native American hunter-gatherer art means it must postdate 1,600 or so, the time after the introduction of the horse by the Spanish. Also, the representation of large, full-body shields in prehistoric Native American art of Montana and Wyoming implies that it dates before the introduction of the horse, since such full shields were deemed impractical for riding. Many other similar

subject matter interpretations are often used to date rock art.

Superimposition of designs – the third major dating method – is a very common means of dating art, one pioneered by the earliest art researchers. This method is mainly for rock art, with a series of art images painted or pecked atop one another, allowing the researcher to understand the sequence of image formation and, thus, attain a relative dating sequence.

Finally, innovations in chronometric dating are leading to a revolution in the absolute dating of art. Advances in radiocarbon dating by accelerator mass spectrometry (AMS) have allowed researchers to sample minute (less than a gram) portions of organic rock art objects and/or organic materials (e.g., charcoal) in rock art panels. It is by this means that the Grotte Chauvet rock art panels in France have been so well dated. Similarly, the lion figure from Hohlenstein-Stadel in Germany was also dated by AMS.

Another chronometric method of dating gaining some popularity is cation-ratio dating. This method measures leaching of potassium and calcium out of rock varnish in comparison to ratios to titanium in the rock (which does not leach). The Legend Rock site in western Wyoming has been subjected to cation-ratio dating to some success (Francis and Loendorf 2002); however, the method requires initial dating of the art by AMS or other methods to measure the rate of leaching within the rock in the microenvironment of the site. So, this method is untenable if one does not previously know the absolute dates of some art at the site (e.g., AMS). At this time, thus, cation-ratio dating is not considered to be as accurate as AMS or standard radiocarbon dating.

Art Interpretation and Sacred Tradition

Study of the interpretation, or meaning, of art has become a major field of study, with a suite of specialized terms used by scholars, defined well by Keyser and Klassen (2001) in their study of Plains Indian rock art of western North America. We summarize some of their key terms here to facilitate an explanation of rock art research and interpretation. Most of the world's hunter-gatherer art is either representational or nonrepresentational. Geometric designs – in the form of circles, lines, or other shapes – are examples of nonrepresentational art, or images of objects that do not occur in nature. Representational art takes the form of either anthropomorphic (humanlike) or zoomorphic (animallike) images but can depict any real object. Often, representational and nonrepresentational images are superimposed upon each other or used in tandem to form the overall composition. In this vein, art often can be depicted in naturalistic, or lifelike (realistic), form or can be abstract (nonrealistic/nonrepresentational) art that lacks obvious interpretation.

For example, Fig. 3 of a petroglyph in Alberta, Canada, is considered to be a naturalistic, representational image of humans (stick figure anthropomorphs) in combat using guns; bullets are represented in animated form by the lines of dots. Somewhat in contrast, the other image from Wyoming (Fig. 4) shows an anthropomorphic zoomorph, a combination often interpreted to represent spiritual transformation of the individual. For hunter-gatherers, this art very often shows an elongated anthropomorph becoming an animal (zoomorph) and/or attached to an animal with a line (here, a turtle), representative of a spiritual transformation. The integrated nature of both compositions contributes to the overall interpretation. Rather than being solitary images or even juxtaposed (a series of isolated, individual, unrelated images on an art object or panel), these particular works of art are coherent compositions with individual attributes that combine to form a larger meaning. In the former image, the meaning is explicit and biographic in its depiction of a battle scene, while the latter image has implicit meaning due to its largely spiritual content; we may never know this latter image's true meaning, other than to say it represents an individual's transformation from human to sacred. We understand the basic principle of the transformation, but not the precise meaning of its experience to the hunter-gatherer artist.

While these terms help us to uniformly describe hunter-gatherer art, whether it be portable material culture, sculpture, or rock art, interpreting rock art is extremely complicated

and subjective to the researchers' theoretical, cultural, and historical background. Ethnographic analogy is a key method of rock art interpretation. In this method, study of contemporary hunter-gatherers provides concepts useful in the interpretation of art produced by hunter-gatherers in prehistory. David Lewis-Williams' (2002) various books and articles on South Africa rock art have been instrumental in the understanding of the spiritual nature of much of the world's hunter-gatherer art. His methods of study have been adopted by many researchers in other areas of the world as well, namely, that much art reflects sacred traditions of hunter-gatherers, especially the concept of self-transformation that often accompanies the human quest for spiritual guidance, as shown above.

Ethnographic analogy contributes to understanding of various possible means of interpreting rock art (Whitley 2011), whether it be art produced for hunting magic (sympathetic magic) to facilitate success in the hunt, to reflect spiritual transformation through a religious experience (transformational magic), or whether the art is simply representational in an art-for-art's sake sense. The major impact of rock art research was to establish the role of symbolic imagery in art, usually through abstract symbols in combination with representational, naturalistic images of animals and/or humans. Through research of hunter-gatherer art, most archaeologists realize that there is probably more than meets the eye in art interpretation. While the image may appear to be representational and mainly naturalistic, its depiction could have hidden, implicit meaning unfathomable to the archaeologist studying the art.

In his study of trance-induced hallucinations among contemporary hunter-gatherers, Lewis-Williams (1984, 2002) identifies several art images that represent events of hunter-gatherer sacred transformation, at least among the San of South Africa. Hunter-gatherer depiction of such spiritual events often shows death (e.g., hunting scenes or bleeding life-forms), mystical flight (e.g., birds or other images of flight), drowning (to reflect the weightlessness of the spiritual experience), or sexual arousal (e.g., erect phallic representation). He argues that these images in combination with more obvious signs of transformation (combination human-animal forms) connected with lines to other animals and abstract forms likely reflect spiritual activity of the individuals. As we have discussed in this section, such images are present in even the oldest examples of hunter-gatherer art, meaning that the representation of this transformative experience (e.g., from human to animal to spirit) is among the most fundamental of human experiences that dates back to our earliest ancestors 30–40,000 years ago. It is this connection between art and sacred tradition that defines our symbolic ability as humans, which defines us as such and which is visible in the archaeological record of hunter-gatherer cultures throughout the world.

International Perspectives

This final section briefly summarizes four aesthetic systems which show the diversity of hunter-gatherer art and sacred traditions found at world archaeological sites, including Northwest Coast Native American art, Upper Paleolithic Europe portable and parietal art, South African San parietal art, and aboriginal art of the western and northern territories of Australia.

Northwest Coast North American Art

In the annals of world prehistory, many hunter-gatherer cultures exhibit characteristics of generalized foragers, including egalitarianism, high mobility, and risk minimization through expansive kinship networks. Hunter-gatherers of the Northwest Coast of North America lived in semisedentary villages of hunter-gatherer-fishers, exhibiting a complex ranked form of social organization, using storage to offset long-term resource stress. Northwest Coast art reflects the hierarchical and organizational complexity of their society (Holm 1965). Northwest Coast art includes a wide variety of mediums, styles, and produced objects. Black, red, and blue/green are the primary, secondary, and tertiary colors, with formlines and ovoids used to represent zoomorphic and anthropomorphic images, often splitting and reshaping the art forms to fit within the space of the produced object

(e.g., a wood box). Among the most commonly produced art mediums are blankets, masks, boxes/chests, bowls, rattles, jewelry, and totem poles (MacDonald 1983; Wright 2011).

Totem poles were (and still are) handcrafted by wood-working specialists, carving household crests, representations of characters in stories, and/or household histories into a tree to be placed in front of houses and ceremonial structures. Production of Northwest Coast art dates back at least 3,000 years, with objects of the tradition recovered at sites like Ozette, Hoko River, and Tse Whit Zen in coastal Washington State (Kirk and Daugherty 2007). At the site of Ozette on the northernmost Washington Coast, archaeologists and local Makah unburied a 300–500-year-old village, including thousands of well-preserved art objects in the Northwest Coast style (Kirk and Daugherty 2007: 106).

Portable art objects and sculptures dominate the aesthetic traditions of Northwest Coast, but rock art was produced as well, including the famous image of Tsagaglalal, or She Who Watches, from the Dalles in Washington State (Fig. 5). The complexity of art produced by Northwest Coast Native Americans reflects the organizational complexity of their society, with hierarchical social organization and craft specialization, rare among hunter-gatherers in prehistory.

Upper Paleolithic Europe Portable and Parietal Art

The Upper Paleolithic period of Europe persisted from c. 40,000 to 10,000 uncalibrated years ago. As introduced above, Upper Paleolithic hunter-gatherers of Europe produced some of the most sophisticated examples of portable and parietal art in prehistory (Leroi-Gourhan and Champion 1982; Conkey 1984). The earliest dated examples – Grotte Chauvet, France (parietal art) and Hohlenstein-Stadel Germany (portable art) – are among the most artistically advanced as well. As described by Jean Clottes in his wonderful book *Cave Art* (2008), Grotte Chauvet contains hundreds of painted and pecked images, including mammoth, bison, lion, rhinoceros, horse, bear, and humans. One painting called the "Sorcerer" depicts a human with a bison head in a transformative composition. Other important parietal art sites in Europe include Lascaux, Altamira, Niaux, Cosquer, Peche Merle, Trois-Freres, and Le Tuc d'Audoubert, all of which are in France or Spain, the heart of this tradition. Portable art is characterized by the famous Venus figurines found throughout sites in Germany, Italy, Spain, and France. Numerous other art objects and sculptures have been recovered and identified at archaeological sites in Europe that date to the Upper Paleolithic period, making it one of the oldest and best

Sacred Traditions and "Art" in Hunter-Gatherer Contexts, Fig. 5 She Who Watches, the Dalles, Oregon, United States

studied prehistoric hunter-gatherer art traditions in the world (Mithen 1996; Bahn and Vertut 1997).

South African San Parietal Art

As reviewed briefly above, David Lewis-Williams pioneered the study of South African San art, especially their parietal art. As shown by the finds at Blombos Cave, art in South Africa is among the earliest in the world. The early innovation of art facilitated a rich prehistory of traditions. The parietal art is particularly wonderful, depicting pictographic and petrographic images of elongated anthromorphs and zoomorphs participating in a wide range of activities, including the sacred trance dance tradition (Fig. 6), hunting practices, and other transformative religious experiences. The eland is the most commonly depicted animal in this tradition, as shown here. Transformative anthropomorphs and zoomorphs in combination with abstract geometric designs and connecting lines denote the spiritual connectedness and compositional nature of many of the murals. Lewis-Williams (1984) argues for the great (Paleolithic) antiquity of this tradition, linking it to early portable art objects that date back 15,000 years. However, he states that the best preserved and most well-dated objects that can securely date the San art tradition are 2,200 years old from Klasies River Mouth (Lewis-Williams 1984: 235).

Australian Aboriginal Art, Western and Northern Territories, Australia

The parietal and portable art of the aborigines of the western and northern territories of Australia is truly unique among world hunter-gatherer traditions (Bardon and Bardon 2004). The art is produced to reflect aboriginal views of the sacred world (Caruana 1993). Visions of the dreamtime are often depicted in aboriginal art, usually accompanied by oral narratives that describe the stories and myths and travels of mythical individuals on their dreamtime journeys through the environment and the sacred world. The mediums for Australian aboriginal art include rock walls and similar lithic landscapes but also include bark paintings and other portable objects. The earliest examples of aboriginal art occur in northwestern Australia. There, Bradshaw figures – small, pictographic, animated anthropomorphic images – are present on lithic landscapes and date to a minimum of 3,000 years ago (Caruana 1993: 157) to as old as the Late Pleistocene (>10,000 years ago). More recently, within the last few hundred years, this region has witnessed the proliferation of wandjina images, an aboriginal term used to describe pictographic anthropomorphic figures that are associated with the sky and water.

These traditions continue into the ethnographic present, with the art and dreamtime tradition

Sacred Traditions and "Art" in Hunter-Gatherer Contexts, Fig. 6 South African San dancers. (Courtesy of Jack Fisher)

remaining important to Australian aborigines. As with South Africa and the Northwest Coast of North America, the continuation of production of these art traditions into the modern era allowed for a better understanding of the prehistoric art's meaning and aesthetic purpose associated with the sacred beliefs of its producers. The art and sacred traditions of hunter-gatherers are often inseparable, since aesthetic values commonly reflect spiritual and cosmological beliefs of hunter-gatherer individuals in prehistory. Several important volumes are available to better understand these topics.

SAFE/Saving Antiquities for Everyone

Paige Brevick
Saving Antiquities for Everyone (SAFE),
New York, NY, USA

Basic Information

Saving Antiquities for Everyone (SAFE) is a nonprofit organization devoted to combatting the illicit antiquities trade, by raising awareness among both academics and the public. By utilizing an active online presence and social media, SAFE facilitates connections between officials, the public, and on-the-ground heritage

preservation efforts. SAFE's primary goal is to raise mainstream awareness and educate the public on current events, legislation, and heritage management projects that influence the global antiquities market.

SAFE operates entirely on a community-led volunteer basis – relying on international co-creative efforts to rally against the destruction of cultural heritage and advocate for the protection of human history around the world. This unique citizen-led approach allows SAFE to respond to issues that are not always addressed in mainstream media. In this way, SAFE serves as a forum where anyone can have a voice to speak out against the illicit antiquities trade and contribute to heritage preservation efforts.

Funded in 2003 in response to the looting of the Iraq Museum, SAFE members have been at the forefront of legislative overhaul in response to wide-scale looting and heritage destruction in Iraq and across the Middle East. Since then, SAFE has expanded to include anti-looting curriculums and online campaigns with country-specific objectives and is launching on-the-ground heritage management campaigns. Through these efforts, SAFE strives to publicize these issues and projects. Fundamentally, SAFE wants to share the message that our archaeological heritage is a nonrenewable resource, worthy of protection and safeguarding for future generations.

Major Impact

Though SAFE is led by archaeologists, all of our content is created by volunteers who generously donate their time to this cause. Many of SAFE's campaigns have been designed during student internships and through volunteer-led initiatives. This volunteer force is the heart of every SAFE project, embodying SAFE's objective to empower the public and enable community-based engagement in combatting the illicit antiquities trade. In response to the devastating effects of the 2015 earthquake in Nepal, SAFE created the #HonorNepal campaign. This campaign called on followers to contribute their personal photographs of Nepal's heritage landscape into an online photo database, archiving community photographs of now lost cultural heritage.

The SAE website [savingantiquities.org] hosts a variety of news resources and articles geared toward safeguarding cultural heritage and combatting the illicit antiquities trade, by connecting the public with easily relatable materials. The *A Global Concern* section represents SAFE's increasingly international outreach. Each page of this section addresses a different country and its unique heritage preservation issues. Soon, SAFE will release the *Toolkits* project, an easily distributed anti-looting curriculum, designed to aid museum educators in discussing ethical collecting and the illicit antiquities trade. SAFE has launched numerous international advocacy campaigns to raise awareness of looting and heritage destruction, such as *Say Yes to Egypt*, *Save Old Kashgar*, and *The Donny George Candlelight Vigil for Global Heritage*, among others. Coinciding with these campaigns, SAFE has written blog posts, distributed posters and buttons, and participated in conferences.

SAFE has also participated in and sponsored many on-the-ground anti-looting initiatives. In early years, *SAFE Tours* offered participants privately guided tours through major art museums, sharing information on the history of ethical collecting and objects of contested origin. These tours challenged participants to reimagine objects without their cultural context, thereby tasking them with recognizing the importance of documentation and object history. SAFE has consulted on numerous anti-looting projects by providing interviews, offering heritage management expertise, and assisting with dissertation research. In 2016, SAFE created anti-trafficking posters for distribution in Belize airports, to alert travelers to the impact and consequences of purchasing looted antiquities. Currently, SAFE is working to partner with on-the-ground campaigns that foster anti-looting education and promote sustainable heritage management across at-risk sites.

Sagalassos, Archaeology of

Marc Waelkens
Sagalassos Archaeological Research Project, Katholieke Universiteit Leuven, Leuven, Belgium

Introduction and Definition

The Pisidian city of Sagalassos is located 109 km north of Antalya (Southwest Turkey) near the town of Ağlasun (Burdur Province). The ruins are situated on the southern slopes of the Ağlasun Dağları in the Western Taurus range at an altitude of 1,490–1,600 m. Although discovered in 1706 by P. Lucas, it was not until 1824 that F. V. J. Arundell identified these ruins as Sagalassos. A detailed study of Sagalassos' ruins and inscriptions was carried out in 1884–1885 by a team led by Count K. Lanckoroński. Neglected and forgotten during the following century, Sagalassos was included in the British "Pisidia Project" by S. Mitchell, who surveyed and mapped it in 1986–1988. Following a small-scale excavation in 1989 supervised by the Burdur Museum, M. Waelkens (KU Leuven, Belgium) obtained full excavation rights in 1990 (Waelkens 1993: 37–41; id. 2006). Since then, the site and its 1,200 km^2 territory (Vanhaverbeke and Waelkens 2003) have become the object of one of the largest multidisciplinary archaeological projects in the Mediterranean (Waelkens 2008). In 2014, after M. Waelkens' retirement, J. Poblome (KU Leuven, Belgium) took over as project director.

Key Issues/Current Debate

Middle Paleolithic to Bronze Age (120,000–1,200 BCE)

Recent intensive surveys in the territory of Sagalassos have indicated that from the Middle (120,000–45,000 BCE) to the Late Paleolithic/Epipaleolithic (to 10,000 BCE), hunter-gatherers were active in the eastern part of the later territory of Sagalassos. They were attracted by the available resources: good grazing for game and chert outcroppings, which they exploited to produce high-quality tools (Vandam et al. 2017b). From the Neolithic onwards, this district apparently no longer saw any human activity until the Late Chalcolithic (3,500–3,000 BCE). However, at the latest from the Late Neolithic (6,500–6,100 BCE), permanent (farming) settlements emerged in the western part of the territory, more specifically in the Plain of Burdur. Initial settlement may have been limited to two major mounds, Hacilar and Kuruçay. Their inhabitants probably practiced small-scale mixed farming (plant cultivation and animal husbandry). During the subsequent Chalcolithic (6,100–3,000 BCE) and Early Bronze Age (3,000–2,000 BCE), periods during which larger mounds coexisted with farmsteads or

hamlets alternated with centuries during which human activity in the valley appears to have been scarce. This may be caused by problems of either recognition or visibility, or social change or environmental shifts (De Cupere et al. 2015a; Vandam 2015; Vandam and Kaptijn 2015; Vandam et al. 2017a, b).

The absence of diagnostic remains makes it difficult to explain why around the start of the second millennium BCE, here as elsewhere in Anatolia, Early Bronze Age mounds were abandoned. They were gradually replaced by a landscape of principalities. At Sagalassos, it has so far proven impossible to associate local Late Bronze Age pottery found at the surface in the western part of the classical city with stratigraphic contexts. Consequently, the suggestion that Salawassa, a Luwian mountain fortress mentioned in Hittite sources around the middle of the fourteenth century BCE, might be a predecessor of Sagalassos (Waelkens 2000) cannot be substantiated. Equally unclear is through which mechanisms the Indo-European Luwian language gradually spread across Western Anatolia from the later third millennium BCE on (Poblome 2012). In any case, the region of Sagalassos seems to have been part of one of the Late Bronze Age Luwian kingdoms (Waelkens 2000).

Early Iron Age and Archaic Period (1,200–500 BCE)

After the collapse of both the Hittite empire and the Luwian kingdoms in the twelfth century BCE, the Pisidians settled the Western Taurus range. They consisted of a number of tribes; each tribe had a distinct dialect, predominantly originating from Luwian. During the Early Iron Age, from c. 1,000 to 800 BCE, there is evidence of increased human activity in the territory of Sagalassos; in fact, palynological and geomorphological research indicates a significant human presence. Around 860 BCE, major deforestation caused considerable slope erosion and corresponding valley sedimentation, lasting for two or three centuries, especially in the western valley systems (Waelkens et al. 2002; Dusar et al. 2012). Here, from the ninth century BCE on, some mountain sites emerged. Around 800 BCE, human presence also reappeared in the eastern part of the territory (Vandam et al. 2017a, b).

The subsequent Archaic period (c. 750–500 BCE) saw the development of central places/principalities with monumental burials, both in the lake district and in the Çeltikçi valley region, in the western and eastern part of Sagalassos' territory, respectively. Protected by smaller, fortified mountain sites, these sites were located in large agricultural plains and situated by natural arteries, connecting them with the southern Mediterranean coast. While these central places would have relied on smaller farming villages or hamlets, palynological evidence of potential human activity in the central part of the territory, with the Ağlasun Valley and Sagalassos, has so far yielded virtually no evidence of Archaic occupation (Poblome 2012; Poblome et al. 2013a).

Classical and Hellenistic Periods (500–25 BCE)

Except for some sites in the eastern part of the territory, most Archaic sites continued to be occupied during the subsequent Classical and Hellenistic periods (Poblome et al. 2013; Vandam et al. 2017a), during which all of Anatolia was incorporated into the Achaemenid empire. Yet gradually, a shift can be observed from fortified hilltop sites to occupation of the lower slopes or even the valley floors. The fortified hilltop settlements had a proto-urban character, yet none would develop into a city. These sites, which now also appeared in the central part of Sagalassos' territory, were all absorbed by Sagalassos between the Early Hellenistic and the early Imperial period.

Systematic occupation of the Ağlasun Valley started in late Achaemenid times, probably from the later fifth century BCE, when two new settlements co-originated, surrounded by smaller farms on the lower slopes (Poblome 2014; De Cupere et al. 2015a; Daems and Poblome 2016: 101). These two sites, Sagalassos and Düzen Tepe, were only 1.8 km apart: Sagalassos on the upper slopes of the Ağlasun Dağları and Düzen Tepe on a plateau located further down the valley (Poblome 2014). Düzen Tepe was excavated by M. Waelkens in 2006–2011 (Vanhaverbeke et al. 2010). Both were self-sustaining communities, dependent on arable farming and animal

husbandry but also developing craft activities (Daems and Poblome 2016). Düzen Tepe, inhabited until the late second century BCE, was a large, densely settled and well-fortified site covering c. 13 ha (Poblome and Waelkens 2011; Poblome et al. 2013a). Its core occupation dates to the fourth and third centuries BCE. A public bakery and a public building, as well as impressive fortification walls – unless these predate the Classical settlement – reflect a well-organized society. The site and its material culture remained virtually unchanged until its late second century BCE abandonment, possibly caused by water shortage (Waelkens and Poblome 2011: 33–56).

At Sagalassos, human activity becomes visible from the late fifth/fourth centuries BCE onwards. The first settlers were likely attracted by the local abundance of water (Steegen et al. 2000; Martens 2006; id. 2008; Waelkens 2016: 323). Although the layout and extent of Classical Sagalassos are not yet clear, initially Sagalassos was thought to have been smaller than Düzen Tepe (Poblome et al. 2013a), despite the fact that it seemed to have already controlled the greater part of the Ağlasun Valley (Poblome 2014). One recent suggestion is that during the fourth and third centuries BCE, the settlement was still a largely independent village that would only have evolved into an urban settlement from c. 200 BC onwards, possibly after extension of its territory (Daems and Poblome 2016). By 188 BCE, this territory reached as far as the southwestern part of the Burdur Plain in the west (Livy XXXVIII. 15; Polybius, Historiae XXI.36.3–4; Waelkens 2004: 444) and the Kestros River (Aksu) in the east. It eventually covered an area of 1,200 km^2.

Eighteen centuries of continuous occupation make it difficult to determine the character of Classical and Early Hellenistic Sagalassos, as its remains are buried up to 4 m below the current surface and covered by later structures. Moreover, if the local building technique was similar to that in contemporaneous Düzen Tepe – rubble plinths supporting mudbrick walls – they may have been largely destroyed by later, more monumental architecture. Nevertheless, residual material dating to this period is found at various locations in the northern part of the city. Structural remains were encountered both below the southern part of the Upper Agora (Talloen and Poblome 2016a: 114–115; id. 2016b: 124–125) and possibly even below the Urban Mansion to the east of it (Uytterhoeven et al. 2013: 376). Late Classical to at the latest Early Hellenistic clay quarrying probably took place in both the northeastern part of the Upper Agora (Daems and Poblome 2016: 97–98; Talloen and Poblome 2016a: 115–116) and in the Eastern Suburbia. As evidenced by the construction of terracing walls, contemporaneous farming was also practiced there along its northern edge (De Cupere et al. 2015b: 174). Just south of the Upper Agora, below the Roman Odeon, a small potters' quarter was active from the end of the third century into the first half of the second century BCE. It reflected a more specialized production process than had been the case in Late Classical – Early Hellenistic times (Poblome et al. 2013b). Overall, an extensive area, ranging from the southwestern part of the Imperial city up to the eastern outskirts in the later Eastern Suburbia, was already being exploited for some purpose (Daems and Poblome 2017: 60–61).

However, a recent suggestion that at the time of its conquest by Alexander the Great in BCE 333, Sagalassos was still a village (Daems and Poblome 2016: 96–98; Talloen and Poblome 2016a: 116, 147) rather than the "not a small city" mentioned by Arrian (Anabasis Alexandri I.28), seems to be contradicted by other evidence. Firstly, traces of pre-Hellenistic activities are already spread over a large part of the Roman imperial city. Secondly, during the intensive urban surveys, Classical to Early Hellenistic pottery was well represented as surface material across an extensive area, mainly in the southwestern parts of the site (Martens et al. 2008; Martens et al. 2012b; Daems and Poblome 2017: 50). This (unexcavated) area appears to contain the earliest domestic structures, including several probable Hellenistic peristyle houses (Uytterhoeven et al. 2010: 294–295). The nucleus of the earliest settlement may be located there.

Arrian wrote nearly five centuries after the event, yet his topographical description of the conical hill in front of the city (the "Alexander Hill"), on the top of which Alexander defeated the

Sagalassians, is so accurate that it must rely on an eyewitness account. It is also hard to believe that Alexander would have given up the siege of Termessos – then the second most important Pisidian town – and moved northwards to capture Sagalassos instead, if that had been a mere village. A fragmentary inscription dated to the late fourth – first half of the third century BCE, i.e., shortly after Alexander's conquest – contains a new law issued following internal strife. Written in impeccable Greek, the new lingua franca, it refers to a local system of government at Sagalassos that cannot be associated with a settlement of the village type. The text identifies Sagalassos as a "polis" with "politai" and elected, rotating magistrates ("archontes," "dikastai"). It also refers to an even older legal system (Waelkens 2018: 3–4; Eich et al. 2018: 21–28 no. 1). Interestingly, the twenty-plus individuals mentioned in the text all still have exclusively Pisidian names (Eich et al. 2018: 28).

From the Early Hellenistic period on, Sagalassos must have rapidly become Hellenized. Five centuries after its capture by Alexander, Arrian described its population as "Pisidians who were thought to be the most warlike of this warlike people" (Arrian, Anabasis Alexandri I. 28). At the time when the Roman consul Cn. Manlius Vulso entered their territory (189 BCE), Livy referred to the Sagalassians as "by far the best warriors in this region" (Livy XXXVIII. 15.7). According to Greek sources, from the early fifth century BCE on, many Pisidians served as mercenaries for the Persian Great Kings or their adversaries. This may have brought them into direct contact with the Greek colonies in Asia Minor, from which the Pisidians adopted Hellenizing influences (Waelkens et al. 2011). As the Sagalassians must have earned their reputation as excellent warlike soldiers before 189 BCE, they may well have been Pisidian mercenaries in the Achaemenid and later Seleucid and Ptolemaic armies. This may be corroborated by the omnipresence of weaponry depicted on cremation urns or bone containers – totally absent at Düzen Tepe – from the later third to second centuries BCE and on public monuments as late as the reign of Claudius (Waelkens 2018: 3). This also fits with the claim on the city's coinage, starting from the reign of Caligula, that it was of Spartan origin, as documented by the cult of the "heros Lakedaimon" (Waelkens 2018: 3 note 33).

In Early Hellenistic times (Waelkens 2004), Sagalassos became part of the realm of the Seleucids (Waelkens 2004). Because the city had refused to welcome Cn. Manlius Vulso after the Seleucids' defeat at Rome's hands in 189–188 BCE, the Romans imposed an enormous penalty (Livy XXXVIII. 15; Polybius, Historiae XXI.36.3–4). The apparent good relations with the Seleucids (Waelkens 2004: 440–444; id. 2018: 4) may also explain why around 300 BCE posthumous Alexander tetradrachms were minted at Sagalassos (Van Heesch and Stroobants 2015). This, it has been suggested, may have represented a measure of active urbanization by the Seleucids in order to facilitate market exchange and ensure the flowback – as taxation – of their silver stocks to the royal treasury (Aperghis 2004: 29–34). However, it is more likely to have been a temporary issue of "proxy Seleucid" coinage in order to pay for short-term military campaigns in the region (Le Rider and de Callatay 2006: 267). The choice of Sagalassos was perhaps inspired by the fact that it was already in full urban development, just like the other main places in Pisidia and Pamphylia, where contemporaneously similar coins were minted for similar purposes (Van Heesch and Stroobants 2015). The recent suggestion by Daems and Poblome (2016) that the Seleucids actually intervened in the urban development of Sagalassos therefore seems unlikely.

Around 200 BCE the center of Sagalassos seems to have shifted northwards, when a new political center, better suited to Hellenized urban settlement, was created around the Upper Agora (Fig. 1). The clay extraction pit in this area was infilled and an agora of beaten earth laid out, seemingly covering an area of roughly 1,000 m^2 (Talloen and Poblome 2016a: 116–118). By the end of the third century, the city had started producing pottery that drew its inspiration from the Cypriot-Levantine area rather than from shapes from the major western production centers (van der Enden et al. 2015: 90–94). This pottery was

Sagalassos, Archaeology of, Fig. 1 Aerial view of the Upper Agora: in the center, the Upper Agora (no. 1). Surrounding it: the Middle Hellenistic building (no. 2), the early Imperial bouleuterion (no. 3); dated to reign of Augustus: the Doric fountain (no. 4), the NE building (no. 5), the honorific columns (no. 6) and the Tychaion (7); in the southwest corner of the square the mid-first century CE prytaneion (no. 8); along the northern edge, the mid-Antonine nymphaeum (no. 9); on the west side, the sixth-century CE monumental staircase to the bouleuterion complex (10); and the sixth-century water basin to the north of it (no. 11). (© Sagalassos Archaeological Research Project)

exported all over the territory of the city, seemingly reflecting Sagalassos' growing political influence over the region (Poblome et al. 2013a: 534). In the Hellenistic period, settlements in the territory became more numerous. Many were relocated from the upper slopes and hilltops to the lower slopes and the fertile valley floor (Vanhaverbeke and Waelkens 2003: 230, 242; De Cupere et al. 2015a: 8).

Between 188 BCE and its incorporation in the "provincia Asia" of the Roman Republic in 133/129 BCE, Pisidia was part of the Attalid kingdom (Waelkens 2004; id. 2018: 5). A large stone structure overlooking the slopes to the southeast of the Upper Agora, currently being excavated, may date to the earlier period of Attalid rule (Fig. 1, no. 2). The suggestion that it represents a market building of the Pergamene type (Talloen and Poblome 2016a: 118–119) cannot yet be confirmed (Waelkens 2018: 5). In fact, the structure – incorporated into a much larger early Imperial complex and rebuilt several times in late Antiquity – seems to be much smaller than previously assumed. Although it may have functioned as a market building, it could also have been a smaller administrative structure, as known from other Pisidian cities (Waelkens 2004: 466).

Towards the late second or early first century BCE, under Roman Republican rule (129–39 BCE), a monumental terrace building (Fig. 2, no. 3) – previously erroneously dated to the Early Hellenistic period (Waelkens 2004: 464–46) – monumentalized the access to the agora from the northeast (Talloen and Poblome 2016a: 119–120). The extant remains of the pre-Imperial city wall are Hellenistic, built around 100 BCE, yet in 189 BCE Livy described Sagalassos as a "well-fortified town in a land where such strongholds were few" (Livy, Historiae XXXVIII.15.7), suggesting there may have been an earlier wall (Waelkens 2018: 4).

Despite extortion by Roman tax collectors ("publicani"), regional wars and piracy on the Mediterranean, by the second century BCE,

Sagalassos, Archaeology of, Fig. 2 The mid-Antonine nymphaeum built c. CE 160–180 along the north side of the Upper Agora (no. 2) and replacing an Augustan predecessor (no. 1). Restored and returned to a functional state in 2010, the monument currently displays copies of original (both corner "tabernacles") and recycled statues of Olympian gods placed in it during the sixth century. Adjoining the fountain to the right, the terrace wall of a terrace building erected c. BCE 100 and pierced by a vaulted opening giving access to a postern running below the city's northern fortification (no. 3); on a higher terrace, the Late Hellenistic Doric temple (no. 4) and the restored Augustan NW Heroon (no. 5). On either side of the nymphaeum, the two northern honorific columns (no. 6). (© Sagalassos Archaeological Research Project)

Sagalassos' built-up area had begun to expand eastward, beyond the fortifications (Martens 2009: 192; Uytterhoeven et al. 2013: 376), and during the Late Hellenistic period also towards the south (Jacobs and Waelkens 2013: 223–224). This was perhaps not only the result of demographic growth, but also the consequence of a "synoikismos" with the by now largely abandoned settlement of Düzen Tepe (Waelkens 2018: 5). In any case, the settlement pattern in the Ağlasun Valley suggests a process of demographic nucleation at Sagalassos during the Late Hellenistic and Early Roman Imperial periods (Poblome 2015: 120–121). Probably during the second or early first century BCE, the city once again issued a limited number of anonymous silver and bronze coins (Van Heesch and Stroobants 2015).

Mark Antony had created a small client kingdom ruled by the Galatian king Amyntas (39–25 BCE), who expanded it over wide parts of Anatolia. However, not all citizens of Sagalassos accepted his rule; one stronghold on the eastern edge of the city's territory even resisted the king until his death. A decree by the "demos" of Sagalassos concerning a Termessian citizen, who had negotiated at this time of serious internal strife, shows that by then Sagalassos possessed a city council or "boulè," which must have convened in a building predating the early Imperial bouleuterion. The highest magistrates were now the eponymous "probouloi," who presided the council (Waelkens 2018: 5; Eich et al. 2018: 28–31 no. 2).

During the short reign of Amyntas, a fountain house of the Greek type (a U-shaped Doric stoa:

Sagalassos, Archaeology of, Fig. 3 General site plan. On the west side, the Julio-Claudian stadium (no. 1) and the southwest domestic quarter, perhaps the location of Classical/Hellenistic Sagalassos (no. 2); in the center, the Upper Agora with the macellum (no. 3), the Lower Agora (no. 4), the Colonnaded Street (no. 5), the Imperial Baths (no. 6), the Urban Mansion (no. 7), and the shrine of the Pisidian emperor cult (no. 8). On the east side, the eastern domestic quarter (no. 9) with the Late Hellenistic fountain house fronting the Neon Library (no. 10) and the theater (no. 11). In the Easter Suburbia (no. 12), the "schola" (no. 13). (© Sagalassos Archaeological Research Project)

Waelkens 2016: 323–324) was built in the by now rapidly expanding eastern domestic quarter of the city (Martens et al. 2008: 136–138; Poblome et al. 2015: 203–205). It captured the water of a local aquifer (Fig. 3, no. 10). A Corinthian temenos in the lower city and a Doric "distyle in antis" temple (Fig. 2, no. 4) – probably dedicated to Zeus – may date to the same period, since the latter's construction on a hill dominating the Upper Agora from the west predated that of the early Imperial bouleuterion (Waelkens 2002: 316–317; id. 2018: 6). The reign of Amyntas also saw a fresh start and even a peak of the local anonymous bronze coin production, possibly related to an increased military presence of the king's troops in the region (Waelkens 2002: 316–317). From now on Sagalassos would issue bronze coins intermittently throughout the Imperial period until the reign of Claudius II (CE 268–270) (Waelkens 2018: 5).

The High Roman Imperial Period (25 BCE – 300 CE)

In 25 BCE the Roman emperor Augustus (BCE 27 – CE 14) incorporated the kingdom of Galatia, including Pisidia, into the Roman Empire. During his reign Sagalassos underwent a complete metamorphosis (Waelkens 2002, 2018; Waelkens and Poblome 2011: 57–98). Augustus' foundation of seven new colonies and settlement of veterans in four existing cities – all located within a 100 km radius around Sagalassos – expanded the potential market for Sagalassos' produce and craft products by up to 60,000 colonists, predominantly from southern Gaul and central Italy (Willet and Poblome 2015: 3, 14). Combined with the city's growing territorial impact and demographic changes, this may have stimulated elite investment (Willet and Poblome 2015: 14) in a new type of tableware (Willet and Poblome 2015: 1–2). Consequently, as early as under Augustus, Sagalassians, aware that the Italian colonists

preferred fine, red-slipped tableware, turned their existing local pottery tradition into an industrial-scale production of "eastern sigillata," the "Sagalassos red slip ware" (Poblome 1999: 314). This new tableware was in all likelihood primarily aimed at external markets, mostly Pisidia and western Anatolia but also reaching central and eastern Mediterranean markets, as far afield as Ostia and Carthage, at least during the first three centuries CE (Poblome 1999; Poblome 2008: 207; Willet and Poblome 2015). The potters of Sagalassos began to expand their activities into a new quarter in the Eastern Suburbia, where the increased output correlated with an increase in production units (thus far 135 kiln locations have been identified: Murphy and Poblome 2017: 62–63; Janssen et al. 2017: 594). The genuine type of sigillata produced here initially combined new elements with regional design traditions, resulting in a specific and recognizable set of shapes (van der Enden et al. 2015: 93). An exponential growth in production took place in Flavian times, peaking in the Antonine period (Willet and Poblome 2015: 9–10). From the second half of the first century CE onwards, Sagalassos' potters switched to more generic Italian-inspired types (Poblome et al. 2007: 228).

In 6 BCE the Via Sebaste was built, connecting the major Augustan colonies with the Pamphylian ports. The city of Sagalassos maintained a stretch of over 42 miles of this important road (Eich et al. 2018: 31–39 no. 3). It offered the city direct access to the Mediterranean, and Sagalassos' elite seized this economic opportunity and invested in agriculture on a massive scale. They burned down large stretches of forest and transformed them into pasture and fields for growing cash crops such as grain and olives. A climatic optimum, starting with Augustus' reign and lasting for several centuries, enabled olive cultivation (previously confined to 900 m) up to an altitude of c. 1,400 m. Heavy-metal trace elements found in consumed animal bone indicate that the city's subsistence requirements for its estimated population of 2,500–3,000 inhabitants (Willet and Poblome 2015: 5; Janssen et al. 2017: 598) could be largely met by the production capacity of its immediate vicinity, although the local environment was heavily polluted by craft activities (Degryse et al. 2004; Vanhaverbeke et al. 2011; Fuller et al. 2012; Poblome 2015: 111–113; De Cupere et al. 2015a: 8–12). During most of the Imperial period, the output of the large territory of Sagalassos may in fact have vastly exceeded the subsistence needs of the rural population, which is estimated to have been anywhere between 6,000 and 25,000 (Willet and Poblome 2015, 6; Janssen et al. 2017, 598). Owners could thus devote surplus production not used for paying taxes in kind (annona) to trade. This explains the numerous mausoleums and expensive sarcophagi found throughout the countryside from the early Imperial period onwards, in which the landed gentry were buried near their estates (Waelkens et al. 2000a: 63, 67; Kaptijn et al. 2013: 78; Waelkens 2018: 6).

In the course of the first century CE, the city almost quadrupled in size (Fig. 3), eventually covering an area of c. 41 ha (Willet and Poblome 2015: 2). From the first century CE on, rich peristyle houses – even with private bath sections – were built in the eastern domestic quarter (Uytterhoeven 2013: 146; Uytterhoeven et al. 2013: 376–378, 392). This urban development necessitated the construction of elaborate urban water supply systems. From the reign of Augustus onwards, two aqueducts, one from the west and one from the east, respectively, provided the new lower city in the south and the expanding eastern domestic quarter with water. The largely rock-cut eastern aqueduct henceforth also fed the partially adapted Late Hellenistic fountain house, from where water was diverted to a new fountain of the Doric order along the north side of the Upper Agora (Owens 1995; Waelkens 2016: 324–328). Although the latter's existence had been assumed, the remains of its lower courses were only identified in 2017 (Fig. 1, no. 4).

During the first quarter of the first century CE, the city center was entirely monumentalized. Towards the end of the late first century BCE, the Middle Hellenistic Upper Agora had been extended to the west and doubled in size (Talloen and Poblome 2016a: 120–121), to form a roughly trapezoidal square covering 2,380 m^2 (Fig. 3, no. 1; Fig. 1). The square was

only paved just before the construction of the southwest honorific arch dedicated to Caligula (37–41 CE). Porticoes flanking the square to the west and the east were part of the same building project (Talloen and Poblome 2016a: 129–135). A portico fronting a row of shops and bordering the agora to the south was equally erected in the first century CE (Jacobs and Waelkens 2017: 177). Under Augustus, the trapezoidal agora obtained a more regular appearance through the construction of a rectangular Doric fountain along its northern edge (Fig. 1, no. 4; Fig. 2, no. 1) and the erection of the NE Building aligned with it in the northeast corner (Talloen and Poblome 2016a: 128). The latter structure, located south of the northeast access to the agora and facing the Middle Hellenistic terrace building, created a right angle, hiding the earlier oblique access (Fig. 1, no. 5). An arched gateway formed the transition between the eastern and the western extremities of the building's north wall, respectively, maintaining the orientation of the old access road and aligned with the new fountain. In mid- to late Augustan times, four nearly 14 m tall honorific columns carrying bronze statues, forming a rectangle, created even more visual regularity (Fig. 1, no. 6; Fig. 2, no. 6; Fig. 4). The two western columns were dedicated by the "people's assembly" (demos), which probably assembled on the square, to two brothers who were the ancestors of the first Sagalassian family to acquire Roman citizenship in the next generation (Waelkens 2018: 7, 9; Eich et al. 2018: 151–152 nos. 66–67). They may have been instrumental in the new layout of the agora. Most likely, one of them was also involved in the construction of a public building replaced by the current macellum southeast of the agora (Eich et al. 2018: 84). The two eastern columns were not adorned by a statue until much later (Waelkens 2015a: 100–102; id. 2018: 7; Talloen and Poblome 2016a: 123–12, 135). Around the same time, a canopy-roofed monument dedicated to the Tyche of the city (Fig. 1, no. 7) was erected in the middle of the square's south side (Talloen and Poblome 2016a: 129, 133–134).

During Augustus' reign, the urban elite was still honored with elaborate honorific monuments,

Sagalassos, Archaeology of, Fig. 4 View from the east of the southeast access to the Upper Agora with in the foreground the southeast honorific arch, dedicated to Claudius in CE 43–46, and adjoining southeast honorific column. In the background, the arch erected by Kallikles for Caligula and rededicated to Claudius in CE 41–42. Next to it the southwest honorific column carrying a statue of Kallikles' paternal uncle. (© Sagalassos Archaeological Research Project)

such as the NW Heroon (Fig. 2, no. 5), one of many on a terrace overlooking the Upper Agora from the north. This monument apparently honored a young aristocrat, who, based on the decoration, may have introduced the Dionysus cult or initiated a Dionysiac festival in the city (Waelkens et al. 2000c; Waelkens 2015a: 99–100).

During the first quarter of the first century CE, a (new) bouleuterion of Hellenistic type – Doric outside and Corinthian inside – decorated with a weaponry frieze, arose on the slope between the Doric temple and the expanded Upper Agora. Accessed from an open courtyard to the north of it (Talloen and Poblome 2016b: 121–127;

Waelkens et al. 2000b: 246–268), it had a U-shaped seating arrangement for c. 220 council members (Fig. 1, no. 3). Around the same time, the Middle Hellenistic "market building" along the agora's southeast corner was incorporated into a larger structure with a central columnar courtyard (perhaps a gymnasion), of which excavation is still ongoing (Fig. 1, no. 2).

In the lower city, a second agora (Lower Agora) with a more commercial character, covering an area of 1,550m^2, was also built during the early Imperial period (Waelkens 2015a: 104; id. 2018: 7). Its orientation was different from that of the Upper Agora (Fig. 5, no. 1); it was aligned with the rectangular street pattern of the new southern urban quarters (Martens 2009: 194). The Augustan period also saw the erection of a small Ionic "distyle in antis" temple dedicated to Apollo Klarios, overlooking the Lower Agora from the west (Fig. 5, no. 3). Through Apollo, the Sagalassians may have worshipped the living emperor Augustus, who had adopted Apollo as his patron (Waelkens 2015a: 110–114; id. 2018: 8). The construction of an odeon (Fig. 6, no. 7), only finished two centuries later and eventually displacing the old council hall, completed the Augustan building programs in this area (Waelkens 2015a: 105–106), most likely all financed by the city proper.

During the reign of Tiberius (CE 14–37), one of Anatolia's oldest and widest colonnaded streets (9.6–10 m wide; 290 m long) was completed and embellished with a monumental gate at either end (Jacobs and Waelkens 2013: 222–235). Purely pedestrian (Fig. 5, no. 2), it connected the city's Lower Agora with the South Gate (Fig. 3, no. 5). Most other streets were also paved during the Julio-Claudian period, covering a very dense

Sagalassos, Archaeology of, Fig. 5 Aerial view from the south of the middle city with the Augustan Lower Agora (no. 1) extended south by a 290-m-long and 9.8-m-wide colonnaded street of Tiberian date (no. 2). Also Augustan are the shrine of Apollo Klarios (and since Vespasian the "urban" imperial cult) (no. 3). Along the north side of the agora the Trajanic/Hadrianic single-storey nymphaeum, renovated under the Severi (no. 4); on the plaza above and behind it, the two-storey late Hadrianic nymphaeum (no. 5). To the east of the agora, the Imperial Baths overlying the Old Baths (no. 6). (© Sagalassos Archaeological Research Project)

Sagalassos, Archaeology of, Fig. 6 Aerial view of the Imperial Baths overlying the remains of the Julio-Claudian Old Baths (no. 1). On the west side, the female bathing circuit (no. 2); in the center, the "marble room" (no. 3) and to the north of it the Theodosian new men's frigidarium (no. 4); on the east side, the partially excavated palaestra (no. 5) and the original cross-shaped old men's frigidarium, converted to a public hall around CE 400 (no. 6). To the northwest of the bath complex, the Odeon (no. 7). (© Sagalassos Archaeological Research Project)

water supply network that also accommodated the houses of the rich (Martens 2006: 182; id. 2009: 193–196). In 2007, the oldest known Roman bath complex in Anatolia was discovered below the second-century CE "Imperial Baths" (Fig. 6, no. 1). Known as the "Old Baths," this building, which measured 1120 m^2 and was already in use by CE 10–30, seems to follow Campanian prototypes (Waelkens and Poblome 2011: 59–60; Waelkens 2015a: 105–106; id. 2016: 328). The most likely explanation for this is the central Italian origin of many veterans in the region.

Augustus' tax reforms based on a population count system directed much of the revenue straight into the imperial treasury. Consequently, the local elite used its resources to embellish the city, often while carrying out urban magistracies. In return, the city honored them by raising dozens of honorific statues (Talloen and Poblome 2016a: 137, 147), which eventually filled both city squares or lined the Colonnaded Street. Following Augustus' death, elite building programs were focused on purely honorific monuments (mainly arches and gates) dedicated to

the emperors and their families. These served both as an instrument for local self-advertisement and as a means of acquiring Roman citizenship and eventually knighthood. Kallikles, a grandson of the aristocrat honored on the northwest honorific column on the Upper Agora, dedicated an arch to the emperor Caligula (CE 37–41) in the square's southwest corner (Fig. 4). In CE 42/43, after the emperor's death and ensuing "damnatio memoriae," he rededicated it to Claudius, topping it with statues of this emperor and his deceased brother Germanicus (Waelkens 2015a: 101–102; Eich et al. 2018: 51–55 no. 8). A few years later, in CE 43–46, the city's demos dedicated a twin arch to Claudius in the southeast corner of the square (Fig. 4), but once more it was Kallikles who erected a statue of Claudius on top of the monument (Eich et al. 2018: 55–57 no. 9a-b). The building inscription of another arch dedicated to Germanicus and Claudius near the NW Heroon shows that by then, Kallikles' family had been granted Roman citizenship (Eich et al. 2018: 57–58 no. 10). They are the first Sagalassians known to have become "cives romani" (as Tiberii Claudii: Waelkens 2018: 9; Eich et al. 2018: 59). As "civis romanus" Kallikles also dedicated an unspecified monument along the main east-west axis of the city to Claudius and Nero, the gods of the fatherland and the demos (Eich et al. 2018: 156–158 no. 71). Shortly after the middle of the first century CE, his father and uncle, as Roman citizens, financed the construction of a public building, probably a prytaneion (Fig. 1, no. 8), in the southwest corner of the Upper Agora. This building, housing the office of the magistrates responsible for the daily maintenance of the city and serving as the city's banquet hall, was excavated between 2012 and 2017 (Talloen and Poblome 2016b: 127–129).

It was probably during the reign of Vespasian (CE 69–96) that T. Claudius Piso, a son of Kallikles' uncle, forged an association between the emperor cult and the games linked to the cult of Apollo Klarios, the Klareia, which he had founded under Nero and which were held in the recently built stadium (Waelkens 2015a: 115; Fig. 3, no. 1). Piso went on to become the city's first Roman knight or "eques" (Waelkens 2015b: 116).

Under Vespasian, another high-ranking family obtained Roman citizenship (as Titi Flavii), following the introduction by one of its members of a municipal cult for the Flavian imperial house, albeit in connection with that of Apollo Klarios and housed in his shrine (Waelkens 2015a: 115–116). The area around the Lower Agora was further monumentalized in late Flavian – Trajanic times. First, the square itself was given Ionic porticoes along its long sides (Waelkens 2002: 347). Shortly after that, the Augustan Apollo temple – which in the meantime had become associated with the municipal emperor cult – was transformed into an Ionic peripteros by the addition of an outer colonnade. The latter's smooth style contrasts sharply with the exuberant local architecture of the Antonine period, but perfectly correlates locally with the transition from the first to the second century CE. The governor Proklos (Proculus) mentioned in the building inscription of this renovation must therefore have been the governor of Lycia and Pamphylia in CE 101–102 (Waelkens 2015b: 188. id. 2018: 9–10) and not one of the homonymous governors of the same province under Antoninus Pius, as recently suggested (Eck 2013; Eich et al. 2018: 71–75 no. 20). An unpublished inscription, reused in the prytaneion, confirms him as governor of that province during that year. In the Eastern Suburbia, around the end of the century, a mid-first-century structure with uncertain function (Fig. 3, no. 13) was transformed into a (semi-)public structure (probably a "schola"), which from the second into the second half of the third century accommodated the communal dining of an association (De Cupere et al. 2015b; Claeys and Poblome 2017).

The reign of Trajan (CE 98–117) initiated a century-long building boom that peaked under Hadrian, Antoninus Pius, and Marcus Aurelius. At some point after the second half of the first century CE, the NE Building on the Upper Agora was considerably enlarged and re-oriented, henceforth facing west towards the Upper Agora, where most likely it had a columnar front (Fig. 1, no. 5).

Its function however remains unclear. Local aristocrats still financed the construction of monuments dedicated to emperors, but now these structures usually also fulfilled a utilitarian function for the urban community. These included no less than five monumental fountains (Waelkens 2016: 328–333) – three of which were nymphaea with columnar screens, the two others fountains were of the so-called tabernacle type (Fig. 5, nos 5–6; Fig. 2) – and a macellum or food market (Fig. 3, no. 3; Fig. 7). This coincided with a second wave of aqueduct building at Sagalassos, as a result of which three new aqueducts supplied the fountains as well as the Imperial Baths (Waelkens 2016: 328–331). The urban elite were particularly keen to fund nymphaea of the tabernacle type, as the alternation of niches in their back walls with projecting columnar "tabernacles" or aediculae provided them with opportunities to erect statues of their founders and family members side by side with those of emperors and Olympians. In CE 116–117, members of the local Tiberii Claudii dedicated an apsidal fountain lined with freestanding columns to the city and to the emperor Trajan near the entrance of the stadium (Waelkens 2016: 328–329 Fig. 6; Eich et al. 2018: 63–65 no. 15). During the same reign, the construction of a monumental fountain bordering the Lower Agora to the north further monumentalized this square (Fig. 5, no. 4). The two-storied fountain, composed of a straight rear wall with two superposed rows of nine niches each, was lined by a two-storied columnar screen of isolated columns, fronted by a drawing basin (Waelkens 2016: 329–330 Fig. 7). However, before it was completed, most of the fountain's upper story was dismantled and the remaining part transformed into the retaining wall of a new plaza at a higher level behind it. The purpose of this drastic intervention was to increase the visibility of a new fountain, built at the back of this plaza, from the Lower Agora (Mägele et al. 2007; Waelkens

Sagalassos, Archaeology of, Fig. 7 View from the north of the central courtyard and tholos-shaped water basin of the macellum, financed by the city. A priest of the emperor cult to Commodus dedicated the surrounding porticoes, during the last decade of his reign. (© Sagalassos Archaeological Research Project)

2016: 330; Waelkens et al. 2017: 448). T. Claudius Piso, the above-mentioned first Roman knight of the city, dedicated this two-storied nymphaeum of aedicular type with projecting side wings to Hadrian (Fig. 5, No. 5). It was completed by his heirs in CE 129–132 (Mägele et al. 2007; Waelkens et al. 2017; Waelkens 2018: 12–13; Eich et al. 2018: 67–68 no. 17; 123–124 no. 49). The dismantled Trajanic nymphaeum on the Lower Agora was hidden behind another fountain – only one storey high and preceded by a columnar screen – of which the easternmost (ninth) niche was removed in approximately CE 120–125. This intervention was necessitated by the construction of the new Imperial Baths to the east of the Lower Agora, as the result of which the square's northeast entrance had to move westward, cutting the eastern extremity of the fountain (Waelkens 2016: 330 Figs. 9–10).

All this frantic building activity resulted from the fact that in CE 117–118, Hadrian transferred northern Pisidia to the province of Lycia and Pamphylia, uniting it with the rest of Pisidia, and accepted Sagalassos as the "neokoros," the officially recognized center of the imperial cult practiced by all Pisidians. He also granted it the honorific title of "first city of Pisidia, friend and ally of the Romans" (Eich et al. 2018, 68–70 no. 19). The city carried this title proudly, including on third-century CE coinage, until the fourth (or early fifth) century (Waelkens 2015a: 126–127, 2015b: 199–202; id. 2018: 10; Eich et al. 2018: 47–49 no. 7). As Pisidia's neokoros, Sagalassos hosted festivals and games, attracting visitors and delegations from all over Pisidia every year. This brought the city additional income and necessitated the construction of buildings, the size of which far surpassed local needs. They included a temple of the Corinthian peripteral type, accommodating the Pisidian emperor cult, which became the largest sanctuary of Pisidia. It was built on a promontory in the southeast part of the city (Fig. 3, no. 8). Although construction started under Hadrian, it was only completed under his successor and therefore dedicated to Antoninus Pius and his entire household (Waelkens 2015a: 120–121; Eich et al. 2018: 68–70 no 19). Henceforth, the Colonnaded Street may have been a procession street linking the two sanctuaries of the emperor cult. Its increased importance possibly prompted the replacement of at least part of the early Imperial Ionic columns with more elaborate Corinthian ones. In late Hadrianic times, the vista along the street was further improved by the construction of the late Hadrianic nymphaeum above the Lower Agora (Fig. 5, no. 5), located in the axis of the street (Jacobs and Waelkens 2013: 232–235; Waelkens 2018: 12).

Another new structure to accommodate visitors to the festivals was the Imperial Baths (Fig. 3, no. 6). Covering c. 5,542 m^2, these were built on top of the infilled Old Baths, which were incorporated into the largely artificial terrace upon which the new bath complex arose (Fig. 6). The monumental entrance of the structure as well as a large open-air palaestra was only discovered in 2012 and partially exposed in 2013–2014. Construction may have lasted until the late Severan period (Martens et al. 2012a; Waelkens 2013, 2015a: 122–123; id. 2015b: 193–195). In 2007–2008, the excavations in the southern apodyterium of the huge men's frigidarium exposed – in a later, secondary setup – the marble remains of six nearly 5 m tall acrolithic statues representing Hadrian (Fig. 8) and his successors Antoninus Pius and Marcus Aurelius and their spouses. It has been suggested that they originally stood in the Antoninus Pius Temple (Mägele 2013: 57–59). However, the inner dimensions of the cella (9.2 × 6.83 m) are less than half of those of other imperial temples with (even less numerous) statues of similar size and could hardly accommodate the three imperial couples. A sunken surface in the cella floor was erroneously associated with a base for these statues (Mägele 2017). Therefore, it is cautiously suggested here that the colossal statues may have been set up in pairs in the large niches of the "marble room" of the new bath complex (Fig. 6, no. 3). This may have been the "aleipterion," a key space where prior to the event, athletes participating in the Klareia/imperial games received the oil to cover their bodies and where the victors were given their prizes (Waelkens 2015b: 196; id. 2018: 11).

A third new structure, a theater replacing a smaller predecessor and eventually seating 7,000

Sagalassos, Archaeology of, Fig. 8 Colossal portrait head, belonging to an acrolithic statue of the emperor Hadrian, sculpted c. CE 120–125 and at that time perhaps displayed in the "marble room" of the Imperial Baths. (© Sagalassos Archaeological Research Project)

(Fig. 3, no. 11), was completed during the later second century (Waelkens 2015a: 121–122).

Around the middle of the second century CE, T. Flavius Severianus Neon apparently became the greatest benefactor in the city's history. Between CE 120 and 125, he built a structure that may have functioned both as a public library and as a dynastic monument (Waelkens 2015c; id. 2018: 12; Eich et al. 2018: 124–127; Fig. 3, no. 10). Neon was a grandson of the man who had introduced the municipal emperor cult at Sagalassos and of a prominent female member of the local Tiberii Claudii. Together with his wife, he may also have financed the construction of the mid-Antonine nymphaeum on the Upper Agora (Fig. 3, no. 9; Fig. 2). This elaborately decorated and single-storied fountain of aedicular type with projecting side wings dates to the reign of Marcus Aurelius. It replaced the Augustan Doric stoa-like fountain (Fig. 3, no. 4; Fig. 2, no. 1) along the north side of the square (Waelkens 2015c: 235–236; id. 2016: 331–332; id. 2018: 13). Whereas the late Hadrianic nymphaeum referred to the emperor and Apollo Klarios (represented by a colossal statue), who were worshipped together in the nearby Apollo sanctuary, the mid-Antonine nymphaeum was dedicated to Dionysos. Two c. 2.5 m tall sculpture groups of Dionysos and a satyr stood in the side wings (Jacobs and Waelkens 2017: 186).

During the last decade of the reign of Commodus (CE 182–192), in commemoration of an imperial victory, a high priest of the emperor cult financed the four porticoes of a food market or macellum on a terrace below and southeast of the Upper Agora (Fig. 3, no. 3; Fig. 7). The central courtyard was paved and a tholos-shaped fountain built in the middle of it by the city (Richard and Waelkens 2012; Waelkens 2018: 13–14; Eich et al. 2018: 81–85 no. 25; 193 no. 105).

The Severan dynasty saw the completion of more than a century of continuous building activity (e.g. Odeon, Imperial Baths). Around CE 200, the Neon Library was renovated (Waelkens 2015c: 238–242) and perhaps incorporated into a new public building adjoining it to the east, of which the function remains unclear (Poblome et al. 2015). Both structures bordered a new plaza above and behind the Late Hellenistic fountain house (Waelkens 2018: 14). All of this may have been part of large-scale renovation of the infrastructure in this area, from the late second to third centuries CE (Martens 2009: 194). Around the same period or shortly after, the Hadrianic single-storied nymphaeum on the Lower Agora saw its entire undecorated upper structure replaced by an elaborately decorated entablature. This carried small Victories, probably referring to the Parthian victories of the Severi, who had recruited soldiers from Pisidia for these campaigns (Waelkens 2016: 333; id. 2018: 14). Along the Colonnaded Street, a high priest of the emperor cult dedicated a large building to Alexander Severus and Julia Mamaea (Eich et al. 2018: 89–90 no. 29). The city's second neocorate (Eich et al. 2018: 91–92 no. 31) was perhaps granted on this occasion.

Although urban survey data do not suggest considerable impact from the third-century CE crisis (Poblome 2006; Poblome et al. 2012: 170), from the 220 s onwards the involvement of the civic elite in financing public amenities gradually declined. However, by the early third century, the urban fabric was already saturated with the full array of urban amenities that were continuously maintained or renovated (Jacobs 2015: 166). Nevertheless, this stagnation in building activity was perhaps also the result of insecurities in the income of the upper crust (shrinking markets, civic instability, invasions) and a shift in focus from imperial to civic causes (Jacobs 2013: 668). This may explain why the higher echelons of Sagalassian society now invested mainly in new games that celebrated their names and association with the Klareia and the imperial cult (Eich et al. 2018: nos 44, 93, 109, 112, 120), as this allowed them to display both civic euergetism and loyalty to the emperor (Stroobants 2014: 541). Many of the agonistic inscriptions and statues of victors were now concentrated on the plaza in front of the late Hadrianic nymphaeum, built by the man who had forged the link between the Klareia and the emperor cult. In the course of the third century, the plaza saw the addition of a balustrade incorporating new bases with agonistic inscriptions on its south side, and around the turn of the century, a portico-shaped structure was added on the west side. Eventually, the plaza also housed statues of emperors (Eich et al. 2018: 147–149 no. 65). The third-century boom in agonistic festivals in Pisidia and Pamphylia also reflected the privileges granted to the region, because it supplied grain and probably arms to the Roman troops for their Persian wars. The sudden popularity of Hephaistos, the divine blacksmith, on coins from Sagalassos and the wider region may illustrate the latter (Talloen et al. 2015).

The Late Roman Imperial Period (c. 300–450 CE)

In c. CE 297 Diocletian divided the empire into new provinces grouped in "dioceses." In the process, he created a "provincia Pisidia," part of the "diocese Asiana." However, while this new provincia included Sagalassos, Diocletian selected Phrygian Antioch-near-Pisidia as its capital (Belke and Mersich 1990: 185). Nevertheless, Sagalassos continued to carry its title of "first city of Pisidia" and was recompensed – probably by Constantius II – with the title of "metropolis" (Waelkens 2018: 14; Eich et al. 2018: 47–49 no. 7; 92–94 nos 33–3). However, it was clear that the city had become to a certain degree less of a regional pole of attraction (Waelkens 2002: 356–358; Poblome et al. 2012: 170; Poblome 2015: 128).

In the third and fourth centuries CE, while cereal and olive cultivation was abandoned in parts of the territory in favor of more reliable livestock herding, the immediate vicinity of the city focused on growing walnut and grapes. Oil and wine were stored in a new type of amphora that from the middle of the fourth century was probably produced on the same estates as the content. Pottery production in the Eastern Suburbia declined (Willet and Poblome 2015: 9; Poblome 2015: 115; Janssen et al. 2017: 594), but it was neither interrupted nor as much reduced as that of many other former ceramic centers (Poblome et al. 2008; Kaptijn et al. 2013: 75, 88–90; Poblome 2015: 109, 114–115, 121–122). Nevertheless, Sagalassos red slip ware never filled the gap left by those centers (Poblome 2006: 207); from the mid-fourth century CE on, some outlying parts of the territory even shifted to other providers for their common and tableware (Kaptijn et al. 2013: 75, 79–92; Poblome 2015: 123–124). During the second half of the fourth century, however, a new line of tableware arose in Sagalassos' potters' quarter, conforming to the "koine" of Late Roman D (Poblome and Firat 2011). A century later, yet more ceramic activity started in this quarter (Murphy and Poblome 2016) and, for half a century, also east of the Neon Library (Poblome et al. 2015: 222–230; Uleners and Poblome 2014), the latter possibly reflecting a general decentralization of craft activities. Until the mid-sixth century CE it saw the production of figurines and mold-made wares (oil lamps, "oinophoroi") with some supra-regional distribution (Murphy and Poblome 2012; id. 2016; Poblome 2015: 115–116).

During the fourth century CE, Sagalassos became the third highest-ranking bishopric of the provincia Pisidia, after the Phrygian bishoprics of Antioch and Philomelion; the first documented bishop attended the Council of Constantinople in CE 381 (Belke and Mersich 1990: 368–369). During this century, the city may have seen some unrest between religious factions. The Neon Library was renovated for a second time, but it was burned down and demolished by a Christian mob some time before the turn of the century (Waelkens 2015c: 242–245; id. 2018: 14–15; Jacobs and Waelkens 2017: 177–178). This destruction also put an end to the public character of the monumental structure adjoining it to the east (Poblome et al. 2015: 215). Perhaps during the interval between the death of the orthodox emperor Valens in 378 CE and the reign of the orthodox emperor Theodosius I (CE 379–395), an Arian faction of the city transformed the Tychaion on the Upper Agora into a monument honoring the western, predominantly Arian, Valentinian dynasty. A generation later, it was rededicated to Eudoxia, wife of the emperor Arcadius (Waelkens and Jacobs 2014: 96–104; Waelkens 2015b: 204–205; id. 2018: 14–15; Jacobs and Waelkens 2017: 178–179; Eich et al. 2018: 97–101 no. 37 a–d). During the second half of the fourth century, the seats of the odeon, which was by now probably used as a more comfortable meeting place for the councilors than the early Imperial bouleuterion, were raised to a higher level, on top of a podium. This intervention protected the spectators during animal hunts and gladiatorial games, for which the building was now also a venue (Waelkens and Jacobs 2014: 117; Stroobants and Poblome 2015: 82). In the course of the fourth century, public inscriptions honoring the local elite gradually became fewer and eventually disappeared (Waelkens et al. 2006: 221–222, 226).

Overall, the fourth to sixth centuries CE represented another period of growth for the territory of Sagalassos. The number and size of villages increased (Vanhaverbeke and Waelkens 2003: 241–283; Vanhaverbeke et al. 2011) as a result of agricultural intensification and a more specialized craft and farming landscape (Poblome 2014), possibly reflecting rural demographic growth (Poblome 2015: 122–125; id. 2015b; Vandam et al. 2017b). During the fifth and first half of the sixth century, more people than ever inhabited the Ağlasun Valley (Poblome 2015: 122). During the fourth and first half of the fifth centuries, Sagalassos also saw its highest degree of specialization in livestock farming, with a marked increase in cattle, an indicator of a general intensification of land use (Fuller et al. 2010; Poblome 2015: 109, 114). As before, pigs were herded in the polluted environment of Sagalassos throughout Late Roman times. However, a drop in heavy metal content in contemporaneous cattle bones implies that beef no longer came from the valleys surrounding Sagalassos – as had been the case before, and once more from the mid-fifth century onward – but from different, less polluted areas in the territory (Degryse et al. 2004). This possibly reflects a higher integration of the rural economy into the urban economy (Vanhaverbeke et al. 2011; Stroobants and Poblome 2015), as well as intraregional economic specialization throughout the territory (Poblome 2015: 111). Although a similar pattern can be observed for ovicaprines, there seems to have existed a greater resilience in shifting their grazing locations (Fuller et al. 2012; Poblome 2015: 113).

The late fourth and fifth centuries CE were prosperous times for the city and left an impact on the urban appearance, as both public and private construction resumed. Theodosius I (CE 379–395) cemented the triumph of Christianity by an Empire-wide prohibition on pagan rituals and the forced closure of temples. Around 400, a new city wall was built, incorporating the by now abandoned Doric temple and adjacent NW Heroon as towers on either side of a new gate. However, as it followed the trajectory of the Early Hellenistic fortifications, it protected only a third of Sagalassos. Despite the use of spolia, many originating from the bouleuterion and Doric temple and some blatantly pagan, its walls were carefully built, especially near gates. This suggests there was no hasty construction caused by a specific threat, but rather the walls reflect a new civic pride (Waelkens and Jacobs 2014: 94–96; Jacobs and Waelkens 2017:

179–181). The Hellenistic fountain house, although partially providing the mid-Antonine nymphaeum with water, was not included in the fortification circuit. Nevertheless, new water-collecting systems and a small but richly decorated fountain were installed inside the new NW Gate (Martens 2008: 253; Jacobs and Richard 2012: 22–23).

During the reign of the Theodosii (CE 379–450), the Imperial Baths underwent elaborate renovation, which changed the function of many rooms. Some walls were clad with new marble and some floors covered with opus sectile, both predominantly made from spoliated material. The "marble room" (Fig. 6, no. 3) became the men's hot water bathing room (caldarium), whereas the colossal acrolithic imperial statues were moved to the southern undressing rooms of the former huge men's frigidarium (cold-water space), now sealed off from the bathing circuit (Waelkens 2013; id. 2018: 15). A mosaic inscription, laid during floor repair work in the early sixth century CE, tells us that this room was now a multifunctional public hall (demosion), also used for communal dining (Fig. 6, no. 6). It is likely that the space rapidly became used for organizing public meals on the occasion of Christian feasts and as part of Christian charity. Shortly after the frigidarium's conversion, its eastern aisle – transformed into a kitchen before the end of the fifth century CE – also accommodated a small wooden theatre, replacing the infilled "natatio." Perhaps the city council assembled here, once the Odeon had become a venue for organizing blood sports. A new men's frigidarium with a new natatio (Fig. 6, no. 4) was created in a former entrance hall (Martens et al. 2012a: 159–164; Waelkens and Jacobs 2014: 111–121).

In the late fourth/early fifth century CE, two older peristyle villas northeast of the Imperial Baths became the nucleus of an enormous urban palace, known as the Urban Mansion (Fig. 3,

Sagalassos, Archaeology of, Fig. 9 Aerial view of the Urban Mansion, built c. CE 400. On the left (north), the public part of the complex (no. 1); on the right (south), the private part (no. 2), between the bath complex (no. 3) and the large peristyle courtyard (no. 4). (© Sagalassos Archaeological Research Project)

no. 7; Fig. 9). Containing a public and a private wing, it was composed of more than ninety spaces on nine different levels. It may have been the residence of a member of a newly emerging super-elite, composed of "principals," "honorati," and bishops. Surpassing the "curiales" (council members) in power and wealth (Waelkens and Jacobs 2014: 121–123), they used their houses rather than public buildings to demonstrate their position in society. Their palatial features were enhanced by luxurious decorative elements such as mosaic floors, wall paintings, and statuary (Uytterhoeven 2014: 425–432; Uytterhoeven et al. 2013; id. 2014: 222–227). Carefully chosen decorative programs highlighted the educational background of the house owner (Uytterhoeven 2009). Whereas city councilors and municipal magistrates still carried all (by now very burdensome) financial responsibilities of their office, members of this new top class earned exemption from taxation by serving in the Imperial administration of the province(s), where they acquired large landholdings beyond their cities of origin.

By now, Christianity had become the predominant religion in Sagalassos (Waelkens et al. 2006; Waelkens and Poblome 2011: 131–152), but the classical culture remained deeply embedded in society, well into the sixth century. In fact, despite the establishment of a bishop by the end of the fourth century, the material culture shows little sign that Christianity at that time had a drastic influence on the city. Temples were abandoned rather than destroyed and their subsequent repurposing ensured their survival until the end of Antiquity (Jacobs and Waelkens 2017: 189). Apart from the destruction of the Neon Library, there is no evidence that clashes between religious factions lead to the fires ravaging in the later fourth century the prytaneion and the upper part of the market building/gymnasium.

Whereas the lower level of the market building was abandoned and infilled and its upper floor rebuilt from scratch for an unknown purpose, early in the fifth century the prytaneion was rebuilt as a three-aisled space and at within a short period lavishly renovated twice after new fires. Sigma-shaped marble tables illustrate its continued use for public banquets (Waelkens 2018: 16). During the same century, the west portico of the Upper Agora fronting a row of shops was also rebuilt (Lavan 2012: 292–295; Stroobants and Poblome 2015: 91). The workshop of a blacksmith and the possible office of a tax collector or a civil servant in charge of checking the value of the currency rapidly encroached within the portico itself (Lavan 2012: 295; Stroobants and Poblome 2015: 91). After being destroyed by the Neon Library fire, the public building adjoining it to the east was subdivided into smaller units. They included a late fourth-century dwelling, and a contemporaneous or slightly later textile and coroplast workshop, active during the second half of the fifth century and the early years of the next century (Poblome et al. 2015: 215–230). These arrangements seem to reflect a gradual change in the urban fabric, with eventually intramural burials, use of former domestic or public areas by craft activities, abandoned plots, and widespread waste dumping. The macellum also underwent overall renovation during the fifth century but operated as a food market until the second half of the sixth century, although one space was already used for waste disposal (Richard and Waelkens 2012: 83–104).

The Early Byzantine Period (c. 450–600 CE)

By the mid-fifth century, dilapidated monuments of the pagan past were being transformed into the city's first Christian basilicas. This is what happened to the abandoned shrine of Apollo Klarios – its cella and peristasis re-erected inside out – and around the same time or shortly later, perhaps also to the Hellenistic bouleuterion (Jacobs 2013: 317; Jacobs and Waelkens 2017: 180–183; Waelkens 2018: 160). Some reused reliefs of Athena and Ares from the bouleuterion in the atrium of the bouleuterion church document a Christian reinterpretation of pagan imagery (Jacobs and Waelkens 2017: 181–182). The church was erected in the former courtyard of the complex, while the original council hall henceforth functioned as an open atrium. These transformations were not symbols of the victory of the new religion; rather they reflect a continuing concern with maintaining the city's aesthetic appearance, as the highly visible structures had become eyesores in the cityscape

(Jacobs and Waelkens 2017: 183). Based on small-scale test soundings, it has recently been suggested that this church was only built around the middle or even in the third quarter of the sixth century (Talloen and Poblome 2016a 142–149; id. 2016b: 121–127). However, the current remains clearly belong to a renovation phase of the church, when a new mosaic in the basilica's aisles and an opus sectile floor in the "bema" replaced an earlier floor covering, possibly that of the original early Imperial courtyard. A second layer of frescoes also covered earlier wall paintings. Small columns for constructing a baldachin over the altar were still neatly arranged against the north wall of the church. Consequently, the test soundings may illustrate interventions postdating the earthquake around 500 CE, the more as half a century later, no more new building programs were developed in the town center (Jacobs 2015: 172). The construction of a monumental staircase linking the Upper Agora directly to the church (Fig. 1, no. 10) during the second quarter of the sixth century (Lavan 2012: 292–295; Jacobs and Waelkens 2017: 188–189) may also belong to a renovation phase of the complex. The church was dedicated to St Michael, who had a large following (the "Michaelitai") at Sagalassos during the sixth century (Jacobs and Waelkens 2017: 182; Talloen and Poblome 2016a: 140). Between the middle of the fifth and the middle of the sixth centuries, at least eight churches (of the tripartite basilica type) were built in the city and its periphery (Waelkens et al. 2006: 220, 224–226, 241–242; Vanhaverbeke et al. 2009: 182; Talloen et al. 2017). Recently, two more were identified, one in the Eastern Suburbia and one in the periphery, dating to the second half of the sixth and the early seventh centuries.

Christian symbols only appear on locally produced pottery around the middle of the fifth century (Talloen and Poblome 2005: 70–77; Jacobs and Waelkens 2017: 183–184), initially still overlapping with Dionysian motifs that remained popular for another century. However, rather than being indicative of the continued vitality of the cult of Dionysos (Talloen and Poblome 2005: 62–63, 68–70; Talloen 2011: 582–584), these images were entirely decorative and narrative, as symbols of hospitality and conviviality, and as such part of elite iconography (Jacobs and Waelkens 2017: 183–184). Sagalassos' potters also produced both anthropomorphic and zoomorphic figurines until the first half of the sixth century, which remained in use into the next century. Although originating from indigenous rider gods (Talloen and Poblome 2015: 73–77; Talloen 2011: 593), they had also been reinterpreted to serve Christian purposes (Jacobs and Waelkens 2017: 184–186, 191).

During the first and second quarter of the sixth century, many structures throughout the city were almost entirely rebuilt on a monumental scale, affecting the urban infrastructure as well as both public and private monuments. The date and nature of these renovations suggest repairs after some catastrophic event, most likely an earthquake, now known to have prompted extensive work on the baths shortly after CE 500. The scale and monumentality suggest that the citizens of Sagalassos were still wealthy enough and willing to restore the city to its former glory (Jacobs and Waelkens 2013: 236; Jacobs and Sterling 2017: 199). On the Upper Agora, most statues – probably toppled by the catastrophe – and their bases were removed (Talloen and Poblome 2016a: 140). Only those honoring the couple which had built the mid-Antonine nymphaeum and those of their relatives were reassembled inside and on the roof of this fountain, of which the eastern half and central niche were rebuilt (Jacobs and Richard 2012: 39). The fountain was thus transformed into a dynastic monument for the original builders' family (Jacobs and Waelkens 2017: 186–188). In all likelihood, the nymphaeum was explicitly Christianized by means of a Christian inscription and decorative elements with crosses. Except for the two large Dionysos-satyr groups in the lateral aediculae, mythological or pagan statues collected elsewhere in the city replaced the original sculpture display. By now, all statues appear to have been considered purely decorative (Jacobs 2015: 190–191; Jacobs and Waelkens 2017: 187).

Although the early first-century CE pavement of the Upper Agora was retained throughout Late Antiquity, the north-west corner of the pavement

seems to have been re-laid in the sixth century (Talloen and Poblome 2016a: 141). A series of holes cut through the pavement of the agora to fix wooden market stalls, as well as a number of "topos" inscriptions, allocating specific spaces to certain salesmen, indicate that the square was now used for commercial activities (Lavan 2012: 328–331; Talloen and Poblome 2016a: 141–142).

During the second quarter of the sixth century, a monumental staircase built over the west portico linked the square directly to the open atrium of the basilica in the bouleuterion complex (Fig. 3, no. 10), after an earlier access route from the south, just behind the prytaneion, had been blocked (Lavan 2012: 289–353; Jacobs and Waelkens 2017: 188–189). During the late fifth or early sixth century, the northern part of the building behind and above the mid-Antonine nymphaeum was subdivided into smaller units with separate entrances and an arcaded front (Jacobs 2013: 634–635; id. 2000b: 279–297). During the first half of the sixth century, a similar subdivision into smaller spaces also occurred in the Northeast Building and in the market building/gymnasium to the south of it, which is still being excavated. In the early sixth century, the north portico of the macellum was rebuilt once more (Richard and Waelkens 2012: 89–99; Eich et al. 2018: 84–85).

During the first half of the sixth century, the Lower Agora was enlarged and the staircase leading up from the Grand Colonnaded Street re-laid several meters to the south (Jacobs and Waelkens 2013: 241–243; Jacobs 2015: 167–171). The porticoes, now serving more as a food court, were re-erected using a diverse collection of recycled material and subsequently subdivided into several small units. The predominantly smaller businesses of the western portico sold snacks as well as wine, while the north side of the east portico housed a five-roomed thermopolium, serving hot food and beverages (Putzeys et al. 2005: 235–236, 2009: 184–194; Waelkens et al. 2007: 508–510; Jacobs 2015: 166–167). By the sixth century, both city squares had thus been converted into open-air markets and may have been more crowded than ever before (Lavan 2012; Jacobs 2013: 635–636). Whereas the partially rebuilt mid-Antonine nymphaeum on the Upper Agora had only kept the original statues of its side wings, most of the statuary display of the late Hadrianic nymphaeum was still found amidst the remains of the collapsed building. This could suggest that it had fallen victim to the same earthquake but was never repaired.

During the same period, the Colonnaded Street itself also saw a substantial phase of repair, including the partial replacement of its pavement and the renovation of the porticoes, now predominantly composed of pillars supporting arcades (Jacobs and Waelkens 2013: 237–240). New decorative monuments adorned the street. One apparently honored Julian the Apostate (CE 361–364), unless the inscribed statue had been re-used and plastered over (Jacobs and Waelkens 2013: 245; Eich et al. 2018: 95–96 no. 35). Immediately south of the agora, at least eight small pagan statues, originating from fourth-century CE domestic contexts, were placed on top of consoles inserted in the new pillars. The mythological statuary in all likelihood had lost its pagan connotations and was interpreted as an adornment (Jacobs and Waelkens 2013: 236–250; Jacobs 2015: 167–171; Jacobs and Sterling 2017). Other streets were narrowed and stripped of their pavements to restore both the water network below them and the street system. Some had their level raised with accumulated debris (Martens 2009: 197).

A crack running the entire height of the south wall of the frigidarium/public hall in the Imperial Baths was repaired and the vaulted substructures supporting the space were infilled. The floor was leveled and covered with a new mosaic. A sounding underneath the floor confirmed an early sixth century CE date for this intervention. The cracked wall veneer was removed, but eventually only replaced by a simple white plaster coating. The western bath section used by women was abandoned (Fig. 6, no. 2), while the original caldarium for men became a service room, considerably reducing the actual bathing section (Jacobs 2015: 166–168). This perhaps also explains the dismantling of a public latrine in the substructures below the abandoned bathing section. Radiocarbon dating shows that some time between c. 420 and 600 cal. CE, the

latrine was converted and used as a container for dung, which, mixed with large amounts of urban waste, produced a fertilizer (Baeten et al. 2012). Although many of these repairs were carried out with building materials from derelict or abandoned structures, they testify to a great sense of monumentality, illustrating that the municipal spirit of old was still very much alive (Jacobs 2015: 166).

Some work elsewhere in the city may also have been earthquake-related. During the late fifth–early sixth centuries CE, the private bath complex of the Urban Mansion was partially dismantled and considerably reduced in size. Several spaces of the mansion were subdivided and changed function (Uytterhoeven 2011: 299; Uytterhoeven et al. 2013: 376). Other changes lack evidence for violent destruction. Around 500 or in the early decades of the sixth century, the dwelling east of the Neon Library burned down. Both the textile and the coroplast workshops were abruptly but consciously abandoned, leaving all material in place. In the course of the same century, however, the whole area was reorganized with the creation of a professional bakery, active into the second half of the century but possibly given up before the end of it (Uleners and Poblome 2014: 91–92; Poblome et al. 2015: 232–238).

There are indications that in the early sixth century the available water supply was reduced through either damage to the aqueducts (Martens 2008: 255–256) or the disappearance of springs because of tectonic activity. The collection of rain or natural runoff water resulting from the melting of snow became important, as shown by the appearance of cisterns throughout the city. However, other evidence suggests that any water shortages were neither dramatic nor life-threatening (Martens 2006: 183; id. 2008: 257–259). On the Upper Agora, the interconnected workshops in the former west portico were transformed into a portico again, fronted by an open water basin (Fig. 1, no. 11) fed by rainwater (Jacobs and Richard 2012: 12–13). The still functioning Late Hellenistic nymphaeum was remodeled into a "castellum divisorium," with its central courtyard and basins leveled with debris to support water pipes (Jacobs and Richard 2012: 56–57). This suggests a change in water usage and possibly a significant retargeting of water resources. The installation of small street fountains during the sixth century confirms that water was brought closer to potential users (Jacobs and Richard 2012: 26; Jacobs 2015: 66–69).

All these renovation activities ended abruptly around the middle of the sixth century, when the program of repair was interrupted in the course of its execution or given less priority, as was the case with the street renovation. Yet the water network continued to function and initially there was still a clear concern for public sanitation (Martens 2009: 197). This sudden change may have been caused by a combination of factors, among which the intermittently recurring bubonic plague (CE 541–542), thought to have killed a third of the urban and rural population of Anatolia. The resulting demographic losses may have led to diminished agricultural yields and famine (Waelkens and Sagalassos Team 2000: 270–271). While urban survey data initially show virtually no impact of the plague in Sagalassos (Poblome et al. 2012: 171), they do suggest much reduced occupational activity during the later sixth and seventh centuries CE (Martens 2008: 249; Waelkens et al. 2006: 230–231; Martens et al. 2008: 139; Willet and Poblome 2015: 3). In 2015, the skeleton of one plague victim was identified at Sagalassos (Van de Vijver 2018: 228, Fig. 14). Recent Bayesian coalescence-based simulations of mtDNA data sets suggest that the sixth/seventh-century CE catastrophic events (earthquake and plague) possibly caused a gradual and temporary decrease, but certainly not a sudden depletion of the population (Ottoni et al. 2016: 2–3). Yet the number of sampled skeletons was very small (24 individuals from the second up to the sixth century CE, one mid-Byzantine skeleton) for a comparison with modern mtDNA sequences from Ağlasun (Waelkens 2018: 19). Other factors with a negative impact may have been climatic change, a decline in long-distance trade, external military threats, and brigandage (Vanhaverbeke et al. 2004; id. 2007: 635–640; Waelkens et al. 2006: 247–248; Jacobs and Waelkens 2017: 176). In CE 535/536, Justinian had to take measures against

Pisidian brigands rebelling against taxation (Justinian, Novellae Constitutiones XXIV, 1). Whatever the cause(s), it is certain that Sagalassos was drastically weakened within a short period of time (Jacobs and Waelkens 2013: 252).

Nevertheless, the city remained the main urban settlement in the region during the second half of the sixth century, even if by now the interpretation of "urban way of life" was very different from that during the high empire (Poblome 2014: 630). Sagalassos gradually lost its urban appearance and eventually gave up all municipal services such as organized waste collection. This coincided with increasing impoverishment and stress on urban subsistence, as farming activities now also happened inside the city proper (Waelkens et al. 2006; Waelkens and Poblome 2011: 153–58). The reuse of spolia became widespread.

The progressive abandonment of the craft and commercial units alongside both agorae indicates that the population quite suddenly had other preoccupations (Jacobs and Waelkens 2013: 252). Shortly after the mid-sixth century, the southern part of the west portico on the Upper Agora was abandoned and dismantled. Only a bakery installed in the southernmost space as well as a bronze workshop in the street next to it probably functioned until the early seventh century (Talloen and Poblome 2016a: 145–146; Jacobs 2015: 173–174). By the mid-sixth century the mosaic floor of the prytaneion had been destroyed and covered with soil. The structure was probably divided into an area for cooking and one for dining, albeit now in a religious context (the "Michaelitai"). On the Lower Agora, only the northernmost taverns in both porticoes functioned until the early seventh century (Lavan 2012: 297; Putzeys et al. 2009: 165; Jacobs 2015: 173–174). The renovation of the Colonnaded Street was never completed. Whereas some shops were already deserted in the later sixth century, others probably remained active until the early seventh century (Jacobs 2015: 172, 174; Jacobs and Waelkens 2013: 251–252).

As indicated above, in the late sixth and early seventh centuries, waste disposal was no longer municipally organized. The basins of some fountains, the corridors and stage area of the former Odeon, abandoned shops along the Lower Agora and the Colonnaded Street all became primary or secondary dumping places for consumption and butchery refuse, and even for pottery waste. Parts of the macellum remained in use until the early seventh century CE, including for craft activities (antler and bone working: Richard 2014: 272). Yet from the mid-sixth century the northern part of the courtyard was used as a dumping ground (Richard and Waelkens 2012: 95–100). Water distribution and sewage systems were no longer well maintained either. The fact that waste was left to rot in full view, producing putrid smells in the very center of the city, suggests a drastic change in mentality from the civic pride displayed only a few decades earlier. The decline in municipal authority eventually affected the network of streets, many of which were ultimately encroached by private structures (Martens 2009: 197–198; Jacobs 2013: 598–612; id. 2015: 171–172; Jacobs and Waelkens 2013: 251–252).

The public hall of the Imperial Baths, no longer used for public banquets, eventually accommodated two large lime kilns and several small furnaces, used to burn most marble parts and smelt all bronze parts of the colossal imperial statues displayed in the same space (Waelkens 2013: 70–71; Jacobs 2015: 172–173). Other parts of the complex were still being used for communal dining around the middle of the seventh century (Waelkens and Jacobs 2014: 117–118). At the latest by the second half of the sixth century, the Urban Mansion had also lost its previously luxurious character. Spaces in both the private and formal areas were now used as storage rooms. Squatters installed themselves in the public part, while in the later sixth century a "xenodocheion" or inn apparently occupied most of the private part of the complex. The mansion's wall cladding and statuary fed a large lime kiln installed in the atrium (Waelkens et al. 2007: 503–508; Uytterhoeven et al. 2013: 376; Jacobs 2015: 174). In the course of the century, the kilns of the coroplast workshops in the Eastern Suburbia equally became lime kilns (Murphy and Poblome 2016: 188–189).

From the middle of the sixth century onwards, Sagalassos red slip ware was no longer made in

the workshops in the city's potters' quarter, but relocated, possibly to somewhere in the countryside. This tableware continued in existence until at least the end of the next century (Poblome et al. 2012: 147, 2017: 304; Poblome 2014: 634). Common wares were also made in the countryside, as before (Poblome 2014: 632). Both types of pottery show that despite a gradual decline in social complexity, Sagalassos still formed part of a wider cultural sphere in Southwest Asia Minor and western Cyprus (Vionis et al. 2009a; Poblome 2014: 635). From the middle of the century, field walls delineating plots of land suggest a return of agricultural and pastoral activities in the Eastern Suburbia. This was perhaps the result of less favorable conditions on the valley floors because of a wetter climate (Poblome 2014: 630; Poblome et al. 2017: 304). By the later sixth century, there is evidence for food cultivation in the immediate surroundings of the city (Vanhaverbeke et al. 2004: 269). Some farming activities (threshing) even seem to have taken place within the urban context, where now there were abundant wild cultivars (Waelkens et al. 2007: 506–507). By now, like many contemporaneous cities, Sagalassos had become more rural, which probably resulted in a sharp decline in public investments (Jacobs 2013: 652–655). However, even in these decades, at least part of the population was not deprived of decent subsistence patterns. Centralized cattle butchering and organized meat distribution continued until the early seventh century. Fish from regional lakes and rivers, the Mediterranean, and even Egypt was imported throughout the sixth and into the seventh century (Arndt et al. 2003; Van Neer et al. 2004), as was the case with vessel glass and wine amphorae from the Levant and elsewhere (Poblome et al. 2005: 227–228; Jacobs 2015: 172). However, the general quality of life had certainly declined considerably (Jacobs 2015: 190–191).

In the countryside, the trend to establish sites in easily defendable locations, starting in the second half of the fifth century CE, accelerated in the second half of the next century (Vanhaverbeke and Waelkens 2003: 250–251, 297–298; Vanhaverbeke et al. 2004: 247–279: 259, 2007: 623). At least until the end of the sixth century and in some cases beyond, the villages in the territory remained occupied and active, with possibly even some degree of rural population growth in the early Byzantine period (Poblome et al. 2017: 304). In CE 535/536, Justinian referred to Pisidia as a region with "large and populous villages," without mentioning any other type of settlement or settlement hierarchy. Rather than just reflecting a self-regulating process of societal change (Poblome 2014: 631), this seems to confirm the image of former cities and towns gradually losing their urban character and no longer being regarded as "cities."

The Byzantine Dark Ages (Seventh to Ninth Centuries CE) and the Middle Byzantine Period (Tenth to Early Thirteenth Centuries)

Eagle owl pellets deposited on the floor of the former public hall of the Imperial Baths, after sections of its vaults had crashed down in an earthquake, provided radiocarbon dates between cal. CE 540 and 620 (with 95% probability) and a peak around CE 590 (De Cupere et al. 2009). A recent re-evaluation of coins found underneath certain destruction layers confirms that the most recent coins were invariably datable to the reign of Phocas (CE 602–610) or his predecessor Maurice (CE 583–602). These include gold coins, which were not usually lost easily and if lost, would have been searched for. This suggests that the earthquake, which virtually wiped out Sagalassos as an urban settlement, took place in or shortly after the early seventh century (Jacobs 2015: 175; Jacobs and Waelkens 2017: 176). Though the destruction was massive, it left virtually no trace in the recent mtDNA analysis (Ottoni et al. 2016), perhaps because some survivors went on living in the valley below. Although most public buildings were left in ruins, the local community continued to execute projects requiring a communal effort, besides developing private initiatives at household level.

The intensive urban surveys identified significant quantities of seventh-century surface material, mainly in the western parts of ancient Sagalassos, continuing into the upper reaches of the Ağlasun Valley (Poblome 2014: 631). The excavations also recognized continuity in

postearthquake occupation at multiple locations around the Upper Agora and in the Urban Mansion until the mid-seventh century (Uytterhoeven et al. 2013: 383; id. 2014: 222; Jacobs 2015: 176, 188; Jacobs and Waelkens 2017: 189–190). There was even an attempt to salvage the Bouleuterion-basilica through the construction of walls on top of earthquake debris to support the collapsing apse (Poblome et al. 2017: 305). Consequently, at least in the seventh century, the early medieval community living among the ruins may have been more sizeable and better organized than previously assumed, even though its material culture was poor compared to that of the early Byzantine phase of the town (Jacobs 2015: 164, 189).

In the course of the seventh century, occupation was concentrated on the promontory near the dismantled shrine of the Pisidian emperor cult, which was eventually fortified separately. Shortly after the earthquake, building elements such as column drums and capitals were rolled against the edges of the Colonnaded Street, showing continuity of some traffic to and from the old city center from the new nucleus (Jacobs and Waelkens 2013: 253). A water channel ensured a continuous freshwater supply from the area around the Upper Agora (Richard and Waelkens 2012: 100–101) to this settlement (Martens 2008: 253; Jacobs 2015: 181). However, probably around the middle of the seventh century or somewhat later, an impressive barrier wall with two towers, perhaps associated with the Arab invasions, permanently blocked the traffic flow to and from the earlier city center, initiating a definite break with all earlier habitation (Jacobs 2015: 177–185).

Sagalassos appears to have lived on as a "kastron," a defensive and administrative outpost within a "thema," on the fortified promontory. Since the mid-seventh century, when these new military districts were created, it had belonged to the Anatolic Theme (Belke and Mersich 1990: 49, 84). It is perhaps mentioned in CE 905 by Constantine Porphyrogenetus (De thematibus XIV, 37) as a kastron of the Cibyrrhaeotic theme (Poblome et al. 2017: 306), to which Sagalassos had been moved during the first half of the eighth century. However, the reliability of this source is questionable (Jacobs 2015: 186). The fortified settlement was continuously inhabited until at least the later eleventh century (Martens 2009: 191; Vionis et al. 2009a, b; Jacobs 2015: 183–185), perhaps even later (Poblome et al. 2017: 308–310). Its abandonment may have been the result of the Seljuk control of the region (Belke and Mersich 1990: 104). Sigillographic evidence possibly documents its growing economic and military importance during the second half of the eleventh century, in the face of this Turkish threat (Poblome et al. 2017: 308–309).

The kastron also housed the see of a bishop, who may even have been involved in the construction of the fortifications (Jacobs 2015: 186). In any case, Sagalassos remained a regional nuclear community of which the bishop participated in various synods until the eleventh/twelfth century. During the ninth century, it had even become the second highest bishopric of the ecclesiastical province of Pisidia (Belke and Mersich 1990: 368–369; Poblome et al. 2017: 306, 309). During the ninth to eleventh centuries, a sixth-century basilica on the Alexander Hill was elaborately renovated (Poblome et al. 2017: 308).

Yet the kastron was not the only spot of the former city still inhabited during the Byzantine Dark Ages and the mid-Byzantine period. During the eighth to twelfth/thirteenth centuries, evidence for building activities and/or occupation is also present at the former temple of Apollo Klarios, converted to a Christian basilica in the fifth century (Martens 2009: 191; Jacobs 2015: 188). During the ninth to eleventh centuries, a smaller chapel was built inside this church (Poblome et al. 2017: 306–308). The use of a cemetery surrounding it could be radiocarbon dated to the eleventh to the thirteenth centuries (Ottoni et al. 2011).

Although from the seventh century on Sagalassos' economy was probably based on dry crop farming and livestock raising, the morphology of its pottery testifies to a continued degree of connectivity (Poblome 2014: 631–632). From the mid-seventh century on, colder and drier conditions, resulting in an increase of dry, open steppe and maquis vegetation, eventually reinforced a shift towards pastoralism (Vanhaverbeke et al.

2009: 183–187; Bakker et al. 2011, 2012; id. 2013: 70–73). Pastoral activities were recently identified on the slopes of the mountains above Sagalassos (Talloen et al. 2017: 391). Yet there is evidence of ongoing cultivation in many valleys within the former territory of Sagalassos until the eleventh/twelfth century (Vanhaverbeke et al. 2009: 183–184; Jacobs 2015: 189; De Cupere et al. 2015a: 9; Talloen et al. 2017: 390; Poblome et al. 2017: 311). In the countryside, life probably continued to be centered on villages, hamlets, and farms, functioning in a landscape in which most former cities were abandoned, reduced in size to kastra or had become mere villages. Evidence from Imperial legislation and casual references in hagiographies show that between the eighth and eleventh centuries, the village had become the fundamental center of the state's fiscal interests and of rural society. Many villages were located in remote valleys or on hill/mountain slopes. Some were new, others were occupied locations of fortified sites dating to the Archaic and Classical/Hellenistic periods (Poblome et al. 2017: 311). It was here, rather than near the city, that manufacture (e.g., of pottery) took place, perhaps to supply the villages (Vanhaverbeke et al. 2009: 177–181; Poblome 2014: 632; Vandam et al. 2017b: 230). A truly pastoral economy with extensive grazing can only be detected from the eleventh and twelfth centuries onwards (Vanhaverbeke et al. 2009: 183–184; Jacobs 2015: 190).

More research is required to establish to what degree the later part of the eleventh century represents a genuine break for the kastron at Sagalassos. All sites with tenth- to eleventh-century material also contained finds from the thirteenth century (Poblome et al. 2017: 310). Sagalassos' last bishop was referred to as bishop of "Agalassu," a name living on in that of Ağlasun. Recent finds suggest some kind of continued community organization at and around Ağlasun, where new settlement activity developed, into the early thirteenth century. This could reflect a partial relocation of the population in the immediate vicinity, after the seventh-century earthquake, and provide an explanation for the genetic pool remaining largely unchanged (Ottoni et al. 2016; Poblome et al. 2017: 310–311; Talloen et al. 2017: 388–389).

During the mid-Byzantine period, a fortress was built on the Alexander Hill (Vanhaverbeke et al. 2009: 182), possibly by the Comneni after they reconquered the region from the Seljuks in the later twelfth century. It was probably the Seljuks who destroyed it in CE 1204, when they took hold of Saparda (Isparta, on the other side of the Ağlasun Dağları), the last Byzantine stronghold in the area (Belke and Mersich 1990: 123, 155). This meant the end of Sagalassos as an organized community (Poblome et al. 2017: 310). However, the cemetery around the former Apollo Klarios shrine and associated with another, as yet unidentified habitation nucleus, remained in use until the middle to late thirteenth century. MtDNA analysis suggests a drastic fall in population in the region, corresponding to the abandonment of the city (Ottoni et al. 2016: 5–8). In the meantime, Ağlasun had become the new regional center. The Seljuk han, built there during the reign of Giyaseddin Kaykhosrau II (CE 1237–1246), the hamam of which is preserved until this day, may have constituted the core (marketplace) of several outlying small-scale permanent or temporary settlements (Vanhaverbeke et al. 2005; Vanhaverbeke et al. 2009: 182). This indicates both continued occupation of the area and a shift in central place (Poblome et al. 2017: 310).

Sahara, Makoto

Naoko Matsumoto
Okayama University, Okayama, Japan

Basic Biographical Information

Makoto Sahara (1932–2002) (Fig. 1) is a Japanese archaeologist. He was born in Osaka, Japan, in 1932. He picked up a piece of pottery in the park when he was a kindergarten child and decided to become an archaeologist. He participated in an anthropology class for junior high school students organized by the Japanese Anthropological Society and was impressed by Sugao Yamanouchi who founded Jomon studies in 1947. He started visiting Yamanouchi at the University of Tokyo to take private lessons and became absorbed in study of the decoration of Jomon pottery. After graduating from the Department of German at the Osaka University of Foreign Studies, Sahara obtained a doctoral degree in archaeology from Kyoto University. After this, he joined the Nara National Research

Sahara, Makoto, Fig. 1 Makoto Sahara. (Photo courtesy of Shin'ichiro Fujio)

Institute for Cultural Properties in Nara and took part in excavations of the Heijo Palace site in 1964. He became the Head of the Center in 1992 at the age of 60 and an Assistant Director of the National Museum of Japanese History in 1993. He was Director of this museum from 1997 until he retired in 2001. He died in 2002.

Major Accomplishments

Although the Yayoi period was the focus of Makoto Sahara's study, the range of his interests was wide and included the origin and lifestyle of Japanese people. The title of his graduate thesis was "The application of the question of handedness to archaeology." Among his unique works is a comparative analysis of prehistoric pictures on the bronze bells from the Yayoi period with children's pictures, undertaken from the viewpoint of art history and psychology. The archaeology of the Wei-zhi was his last work. He used to comment that he leaned the method of fine observation from Sugao Yamanouchi and how to construct theory from Yukio Kobayashi.

Makoto Sahara strongly insisted that archaeology should not be for a limited number of specialists but for the public. He advocated an accessible and interesting archaeology. He tried to use simple, plain words instead of academic jargon in his writing and suggested that other archaeologists to do the same. In order to make archaeological data and interpretations available to the public, he worked hard to establish and/or empower museums and to protect and preserve archaeological sites, such as the Yayoi settlement site of Yoshinogari, Saga prefecture. When he retired in 2001, Sahara donated about 7,000 of his own books to the library of Chatan town in Okinawa prefecture.

Makoto Sahara's research into the origin of warfare had implications in terms of contemporary warfare. His analysis of stone arrowheads from the Yayoi period concluded that arrowheads as weapons developed during the Yayoi period as evidence of weapons for killing people did not exist in the preceding period. Based on this data – and with potential lessons for modern warfares in mind – Sahara insisted that we should be able to stop warfare because human beings lived without it until recently (in terms of an archaeological time frame).

After Makoto Sahara's death, a collection of his works was assembled by Hiroshi Kanaseki and Hideji Harunari and published in six volumes in 2005 as *The works of Makoto Sahara*.

Saito, Tadashi

Makoto Tomii
Centre for Cultural Heritage of Kyoto University, Kyoto, Japan

Basic Biographical Information

Saito Tadashi is a Japanese archaeologist and an Emeritus Professor of Taisho University. He was

born in Hokkaido in 1908 and has lived to be over 100 years old. When he was one year old, his parents moved to Sendai in the northeast part of Japan. In 1921, Saito Tadashi entered junior high school (in the old system of education, almost equal to the high school in the present educational system), and during his junior high school days, he loved to walk around watching the local customs and manners and sometimes collecting artifacts on the Daigi-gakoi shell midden of Jomon period. In 1926, he entered Second High School (in the old system of education, equal to the half stage of an undergraduate degree in the present educational system) in Sendai. There, he organized a studying club for students who were interested in field surveys, with Nobuo Ito, who would later become the first professor of archaeology in Tohoku University. As a member of the club, he took part in the excavations of Daigi-gakoi shell middens by Sugao Yamanouchi in 1927, and in 1929 he learned from Dr. Yamanouchi about how the cord-mark decoration had been made on Jomon pottery. Saito Tadashi's first paper was published in 1927 as a report on that shell midden. He subsequently wrote papers on folklore for the journal edited by the great folklorist, Kunio Yanagita.

Following Yanagita's advice, Professor Saito chose to study at the Department of Japanese History of The University of Tokyo in 1929. He also attended various lectures in different faculties such as anthropology, prehistory, and architectural history. During this period, he helped to edit the archaeological journal issued by The Imperial Museum, *KokogakuZasshi* (*The Journal of the Archaeological Society of Nippon*), which led him to have broad knowledge and a large network of contacts. In 1932, he wrote his bachelor dissertation on Japanese ancient mortuary practices. He then went to Kyoto University to learn archaeology from Kosaku Hamada, who made him a junior assistant (1932–1935). From 1933 to 1940, he undertook many excavations and surveys in and around Korean Peninsula. He served as a curator of the museum in Gyeongseong in the second half of his overseas mission. This experience would come to fruition in 1955 in his doctoral thesis on the Silla culture.

After returning to Japan, Professor Saito worked in the Ministry of Education and Culture for more than a quarter century (1940–1966), travelling throughout the Japanese Archipelago to conduct cultural heritage management by inspecting archaeological sites. This included his contribution as a governmental officer to facilitating the excavation of Toro in 1948 in which an interdisciplinary team systematically investigated a prehistoric paddy field for the first time, and through which establishment of the Japanese Archaeological Association was promoted. In 1955, Professor Saito received a doctorate from The University of Tokyo, and he started to give lectures there in 1962. He then became a professor of the Faculty of Letters at the university, 1 year before he left the Ministry of Education and Culture. In 1969, he left the university on reaching retirement age and was invited as a lecturer to Taisho University. In the next year, he became a professor, and in 1983 he became an Emeritus Professor of the university.

Major Accomplishments

Professor Saito wrote a large number of books, ranging from the history of archaeology, through Buddhism archaeology and archaeological methodology, to paleology. In his work he placed importance on the following: (a) making full lists of archaeological sites; (b) making a reference list of archaeological books, papers, and other writings; and (c) making comprehensive collections of the information, drawings, and photos of archaeological objects. He has never shirked such basic works and regarded them as essential to the discipline. One of his conspicuous accomplishments is thorough and comprehensive research on the history of archaeology. He once said that he had a sense of mission in studying the history of archaeology because he had graduated from a Department of Japanese History (1997b).

Professor Saito had made every effort to preserve archaeological sites during the decades of his career when he was with the Ministry of Education and Culture. His outstanding contribution to cultural heritage management was to protect significant national heritage sites from military,

political, and economic pressure even during and immediately after World War II. It included the development of a Navy military base planned on the location of a shell midden, the construction of a railroad besides a castle for military use, and manganese mining by the local conglomerate planned below a tumulus. These episodes demonstrate his strong sense of responsibility for archaeological materials.

Professor Saito published a textbook on archaeology, *Koko-gaku no Kekyu-ho* (*Methods in Archaeology*), in 1950. A considerable amount of data had been collected since the first textbook of archaeology in Japan was written by Kosaku Hamada in 1922, but a systematic introductory book of archaeology had not been produced for decades. Saito's textbook followed the style of his master of archaeology, Hamada, and looked like a revised edition of Hamada's book, *Tsuron Koko-gaku*, together with upgraded appendix such as a full glossary, comprehensive references, and extracts of relating laws. Saito's practical experience in the Korean Peninsula and his broad purview on ancient remains obtained as an officer of the Ministry of Education and Culture possibly enabled him to produce this significant book for beginners in archaeology, not later than five years after the defeat of the WWII.

In practical archaeology, Professor Saito takes a comparative approach to study of the ancient East Asian cultures based on his broad knowledge and experience of archaeology there, accumulated since the 1930s. The products of his work include several books on ancient Korean culture, including his doctoral thesis. His interest in burials and temples was combined with knowledge of historiography and paleology, making him a prominent figure in historical archaeology. Above all, his achievements in the archaeology of Buddhism are unparalleled.

Salazar, Noel B.

Noel B. Salazar
Cultural Mobilities Research (CuMoRe),
University of Leuven, Leuven, Belgium

S

Basic Biographical Information

Noel B. Salazar is a Belgian-Spanish anthropologist who received his Ph.D. in Anthropology from the University of Pennsylvania (USA). He is currently Research Professor at the Faculty of Social Sciences of the University of Leuven (Belgium), where he founded the research cluster Cultural Mobilities Research (CuMoRe). He teaches in the anthropology program and the interdisciplinary heritage management module. In addition, he

is Visiting Professor at the Faculty of Foreign Languages and Literatures of the University of Bergamo (Italy).

Major Accomplishments

While at the University of Pennsylvania, Dr. Salazar experienced firsthand the benefits of transdisciplinary research. His involvement within the Department of Anthropology's "Public Interest Anthropology" taught him the necessity of bridging the divide between academia and the wider public. Together with archaeologist Benjamin W. Porter, now Director of the Phoebe A. Hearst Museum of Anthropology and Associate Professor of Near Eastern Archaeology at the University of California at Berkeley, he applied the public interest perspective to heritage tourism. For this work, he was awarded with a Student Achievement Award from the National Association for the Practice of Anthropology. Understanding the changing meaning and value of cultural heritage, both material and intangible, is still high on his research agenda. It forms part of Salazar's broader work within the field of critical heritage studies.

Dr. Salazar's research interests include anthropologies of mobility and travel, the local-to-global nexus, discourses and imaginaries of Otherness, heritage interpretation, cultural brokering, and cosmopolitanism. He has conducted fieldwork at world heritage sites in Indonesia and Tanzania. His anthropological work synthesizes ethnographic findings with conceptual frameworks developed within anthropology, sociology, geography, cultural studies, tourism studies, philosophy, and psychology. Dr. Salazar is particularly interested in disentangling the connections between tourism, heritage, and human mobility.

Dr. Salazar has won numerous grants for his innovative research projects, including from the National Science Foundation, the European Commission, and the Research Foundation Flanders. He was involved as expert collaborator in the first UNWTO study on tourism and intangible cultural heritage and the World Heritage Tourism Research Network international survey on the heritage of the Great War, 1914–1918.

Internationally, Dr. Salazar serves as Secretary-General of the International Union of Anthropological and Ethnological Sciences and Chair of the IUAES Commission on the Anthropology of Tourism. He is Past President of the European Association of Social Anthropologists. In addition, Dr. Salazar is on UNESCO's and UNWTO's official roster of consultants and an expert member of the ICOMOS International Cultural Tourism Committee (with fieldwork missions to Samarkand and the Seychelles) and the UNESCO-UNITWIN Network "Culture, Tourism and Development" (with fieldwork missions to Barcelona, Buenos Aires, Salta, Libreville, and Haifa). In Belgium, he is a member of the National Consultation Panel of the European Commission's Joint Programming Initiative on Cultural Heritage and steering group member of the University of Leuven's interdisciplinary Cultural Heritage Task Force.

Dr. Salazar is the author of several books and numerous peer-reviewed articles and book chapters on the anthropology of heritage tourism (see References). He is the editor of the *Worlds in Motion* (Berghahn) and *Anthropology of Tourism* (Lexington) book series. Dr. Salazar sits on the editorial boards of, among others, *American Anthropologist*, *Annals of Tourism Research*, *Journal of Sustainable Tourism*, *Pasos – Revista de Turismo y Patrimonio Cultural*, and *AIBR – Revista de Antropología Iberoamericana*.

Saleh, Fathi

Fathi Saleh
Department of Computer Engineering, Cairo University, Cairo, Egypt
CULTNAT Center for Documentation of Cultural and Natural Heritage, Giza, Egypt

Basic Biographical Information

Dr. Saleh graduated from the Faculty of Engineering of Cairo University and received his Ph.D. from the University of Paris, France. His main interest is the application of the new technologies in the different fields of cultural and natural Heritage. He is currently professor of computer engineering at Cairo University. From 1995 to 1997, Dr. Saleh occupied the position of cultural councilor at the embassy of Egypt in Paris, and from 1997 to 1999, he was Egypt's ambassador to UNESCO.

Major Accomplishments

Dr. Saleh is also the president of Herimed (Association for the Documentation, Preservation and Valorization of Euro-Mediterranean Cultural Heritage). He is a member of the Supreme Council of Culture and of the Board of the Director of the Supreme Council of Antiquities, as well as a member of "Institut d'Egypte."

Dr. Saleh founded the Center for Documentation of Cultural and Natural Heritage (CULTNAT) in 2000 as a national center for documentation of different aspects of cultural and natural heritage of Egypt. CULTNAT is part of Bibliotheca Alexandrina and is supported by the Ministry of Communications and Information Technology. Dr. Saleh currently holds the position of CULTNAT's founder and emeritus director.

In the field of cultural heritage, CULTNAT has documented different aspects of tangible and intangible heritage. One of the major projects in tangible heritage has been building the Archaeological Map of Egypt for which the center has won the Stockholm Chalange Award in 2004. CULTNAT has a series of publications in every field of heritage such as atlases for every region in Egypt with all archaeological sites included, works of the Egyptian musicians, contribution of Arab Civilization in sciences through old manuscripts, the presidential palaces, etc.

A major study was carried by the center and headed by Dr. Saleh entitled "A strategic approach to Egypt's Cultural Heritage." This study was done upon request from UNESCO. The study shows the different steps to be followed in order to properly manage Egypt's cultural heritage.

Dr. Saleh also managed to establish a masters degree in cultural heritage management (CHM) in association with the French University in Cairo.

Dr. Saleh has won several international awards. In Qatar, in 2010, he received the "Information Systems Expert First Award" from the Arab Towns Organization. In 2010, he won the award of ARCHAEOLOGICAL 2.0 from the "Il Congreso Internacional de Arqueologia et Informatica Grafica, Patremonio e Innovacion" held in Seville, Spain, for his work on "Virtual Representation of Egyptian Cultural Heritage."

Besides these awards, he won the World Summit Awards for different heritage contributions three times. The first was in Geneva in 2003, the second was in Tunisia in 2005, and the third was in Abu Dhabi in 2010.

Sambaqui Research in Brazil: A Review and Recent Trends (Coastal Archaeology from Southern Shores of Brazil)

Maria Dulce Gaspar[1] and Paulo Deblasis[2]
[1]Departamento de Antropologia, MUSEU NACIONAL/UFRJ, Rio de Janeiro, Brazil
[2]Museu de Arqueologia e Etnologia (MAE), Universidade de São Paulo (USP), São Paulo, Brazil

Introduction

Sambaquis (from native Tupi language, literally meaning *shell mounds* or *concheros*) are archaeological mounded sites distributed all over the Brazilian coast, concentrating mostly at ecologically patchy areas involving brackish waters, mangrove, and forests such as lagoon, bay, and estuarine inlets, including coastal islands. These sites achieve impressive dimensions especially toward the southern shores, where they may reach up to 70 m height and 500 m width (Prous 1992; Gaspar 2000). They usually display heterogeneous stratigraphic sequences, intercalating expressive shell layers to darker strata richer in organic materials, including abundant funerary structures in specific portions of the mound. In fact, several burials are reported in most sambaqui descriptions, disposed in specially prepared places, frequently accompanied of artifacts, food offerings, and hearths (Gaspar 1998, 2000; Gaspar et al. 2008, 2013; Klökler 2014) (Fig. 1).

Even though constantly present in Brazilian archaeological literature since the nineteenth century, the meaning of the sambaquis as archaeological structures is still poorly known, and modeling coastal occupations all along the extensive Brazilian coast is just at the beginning. Systematic studies have started only on the 1950s, focusing more intensively at the southern Atlantic shores, from Rio de Janeiro to Santa Catarina. Regional approaches are rare, prevailing typological descriptions or site-specific reports. Only recently systematic and articulated studies about the relations connecting sambaqui regional settlements and dynamic coastal environments have taken place, though recognition and analysis of this theme appeared in former studies.

Traditionally seen as remains of successive camping locations of very mobile mollusk gathering and fishing bands, sambaquis have occasionally been described as places of residence or mortuary structures. The great diversity of sambaqui sites, nevertheless, suggests a certain amount of functional variability still to be adequately explored. Only recently sambaquis have been recognized as intentionally built structures, full of symbolic signification to their builders.

Despite arguments favoring coastal/hinterland connections, Gaspar (1994) suggested that, at least in Brazilian central southern coast, these sites are remains of societies endowed with proper cultural identity, quite distinctive from other hinterland cultures and traditions. Moreover, such an identity seems to be common to most of the extensive Atlantic Brazilian coast.

Sambaqui Research in Brazil: A Review and Recent Trends (Coastal Archaeology from Southern Shores of Brazil), Fig. 1 Sambaqui Garopaba do Sul, Santa Catarina

Two multidisciplinary research projects aiming at the regional scope of sambaqui occupation and, at the same time, the formation processes involved in mound building have changed the sambaqui research scenario since the 1990s (Gaspar et al. 2008, 2013). Studies on Quaternary natural landscape evolution and human occupation patterns were integrated by means of environmental and archaeological approaches, teaming up researchers and specialists from a number of institutions. One of these projects took place in the southern shores of Santa Catarina, at the lagoon/strand plain area between Laguna and Jaguaruna, and the other at the Lakes Region from Rio de Janeiro, extending northward from Guanabara Bay to Cabo Frio (DeBlasis et al. 1998; Fish et al. 2000; Gaspar et al. 2013; Fig. 2). In both projects, a regional approach using systematic dating and careful stratigraphic profiling, together with horizontal expositions in a few sites, allowed for both the analysis of the regional settlements and the careful study of site formation processes in some key contexts.

Two mounds stand out as prominent foci of research. Jabuticabeira II, a large shell mound located in the southern Santa Catarina shores, has been excavated between 1996 and 2006. Several Brazilian and foreign researchers and students have been working on it, and the studies at this mound have had an important role regarding the expansion in the investigation of sambaqui formation processes, bringing in unprecedented new approaches and insights, taking new interdisciplinary research avenues still open today (Klökler 2014; Villagrán 2010). The other mound is Sernambetiba, at the northeastern part of Guanabara Bay, Rio de Janeiro. This site was excavated in the 1980s (Heredia et al. 1982), leaving behind open areas that have, recently, been carefully reexamined with fresh eyes (Bianchini 2015). Thus, most examples used in this text will come from these areas and sites. The other areas will be but quickly appreciated, since they have been less investigated but with very interesting recent contributions.

Sambaqui Research in Brazil: A Review and Recent Trends (Coastal Archaeology from Southern Shores of Brazil), Fig. 2 Sambaquis distribution along the Brazilian coast

Early Research: Evolutionary Perspectives

Scientific interest in sambaquis has been present since the beginning of archaeology in Brazil, and these shell mounds constitute a research theme that has remained active since the nineteenth century. They have been reported from early sixteenth century, having furnished ever since tons of shell for lime production. In fact, most of the first coastal colonial settlements have made extensive use of it for paving and construction, and massive mound destruction has ended not before the 1980s. Economic interest aside, early researchers were puzzled by their large dimensions, as well as the conspicuous presence of human burials, sometimes accompanied by superb sculptures in stone and bone. In fact, these faunal-rich shell mounds, highly visible on the coastal plains along the Brazilian shores, sometimes deliver hundreds of burials per site, appearing frequently as they were mined.

Despite these undisputable archaeological features, the question whether these mounds were natural or human-made phenomena has dominated the debate up to Leonardos (1938), who established sound criteria for distinguishing *sambaquis* (human-made mounds) from the natural shell beds, also conspicuous throughout Brazilian coast. On the next decades, research on these mounds has multiplied and diversified; in the 1960s and 1970s, they have been extensively excavated and dated, and the first technological and stratigraphic studies appeared, as well as the first modern bioanthropological analyses. Following the strict historical-cultural approach then in vogue, sites have been organized into phases, and some different coastal traditions have been created (Prous 1992; Gaspar et al. 2013).

Research has focused mostly on identification, quantification, and sizing of the specimens directly responsible for the volume of the mounds; particularly as regards their most visible components, shells of *Anomalocardia brasiliana*, *Ostrea* sp., and *Lucina pectinata* are thought of as food remains and taken as the staple diet of the sambaqui mound builders. In Santa Catarina and Rio de Janeiro, compositional phasing clearly revealed a shift from earlier shell mounds to later dark earthen deposits rich in fish remains and reduced amounts of shell, where the downsizing of shells was taken as evidence for the exhaustion of local resources. These darken layers are frequently deposited over the shell mound in stratigraphic sequence and occasionally also displaying ceramics.

This approach stands at the basis of the long-standing interpretive perspective of these people as shellfish collectors that, lately, have become mostly fishers (Prous 1992). Following this evolutionary perspective, economic (and social) changes derive from environmental transformations due to climatic and sea level oscillations, affecting the availability and distribution of resources, thus leading to high mobility of small bands of shellfish collectors across coastal areas. Mobility, in this way, has been used as explanation for the mounds' complex stratigraphic sequences, interpreted as successive camping episodes. Thus, large amounts of accumulated food debris has led to interpret these sites as habitational, despite the also large amounts of burials, that have led earlier researchers such as Wiener (1876) and Duarte (1968) to think about them as funerary monuments.

Human remains recovered at the excavations (with interest almost exclusively in the crania) were taken to physical anthropologists that, in Brazil, were very much influenced by deterministic racial theories from nineteenth- and early-twentieth-century French and German authors (Seyferth 1995). Until the first half of the twentieth century, the goal of most archaeological excavations was to produce skeletons used to establish the human physical types considered representative of the past. Human bones, particularly skulls from *sambaquis*, were analyzed apart from their original archaeological context. The *sambaquis* were considered merely as *jazidas* (or mines, a term used widely at the time) from which the bones – the sole focus of anthropological interest – were extracted.

The impressive small sculptures in bone and stone recovered at the sambaquis are relatively rare (only about 300 pieces have been reported), not bigger than circa 40 cm long. They have been acknowledged since the nineteenth century, when some authors (e.g., Lacerda 1885) have considered them too sophisticated to be created by such a "primitive culture," being probably crafted by later civilizations. Prous (1992) calls attention to their elegant and beautiful design, noting that most of these sculptures have come from mound dismantling; the very few excavated pieces are securely associated to funerary contexts. Some exhibit geometric designs, but sea creatures, such as ray, shark, whale, dolphin, and anchovy, are among the most commonly represented in the effigies, an evidence of the deep connection that sambaqui societies have with the aquatic world (DeBlasis et al. 1998). Flying species (albatross, owl, kingfisher, bat) and terrestrial species (armadillo, turtle, alligator, penguin), among others, are also depicted. Very few of them have anthropomorphic figurines, eventually evoking a human/animal entity. Prous (1992: 102) refers to these sculptures as depicting "an animated world, creatures that swim, run and fly, can be taken by surprise having sex" (Fig. 3). Some sea creatures are so realistically depicted that their anatomic details allow for species identification. Terrestrial animals and fowl are usually less realistic (with some exceptions), sometimes just evoking bird or mammal morphology.

Most of these sculptures have a cavity in the ventral face, suggesting a relationship toward fertility and reproduction, and Prous (1992) points out that several pieces have sexual organs represented or have phallic extremities. One sculpture depicts fishes copulating; others show birds about to do it; another one depicts a bird with four younglings in the nest. The geographical distribution of these sculptures is exclusive of the southern shores, between São Paulo and Uruguay. This has led Prous (1992: 223) to

Sambaqui Research in Brazil: A Review and Recent Trends (Coastal Archaeology from Southern Shores of Brazil), Fig. 3 Rock sculptures of sambaquis

consider the existence of an ideological unity along that area, evinced by thematic recurrence and rigid stylistic rules, suggesting some degree of endogamy. In contrast, the remaining lithic industry was described as simple, "primitive," because of being cobble-based, with a large number of used but not technologically modified pieces, and little finishing, except for a variety of polished ax blades (e.g., Bryan 1993).

The Brazilian archaeological scene by the 1960s to the 1980s was marked by the nationwide North American-influenced PRONAPA project, with strong historical-cultural theoretical orientation, mostly concerning regional approaches to the study of ceramic and preceramic hinterland occupations. In contrast, French archaeological missions, and their local followers, conducted rock art studies and extensive excavations on punctual sites (Barreto 2000). Occasional sambaquis have been excavated in French structuralist-based style (*décapage*), while others have been tested in a prospective way, in order to provide for chronological sequences and detect sociocultural changes by means of analyzing economic (diet) variability in the faunal record.

Figuti (1993) has expanded this approach by introducing sampling methods (thus allowing for quantitative analysis) and investigating the relationship between the preserved bone or shell parts and the edible amount of food therein represented. His analysis made it clear that fishing has always been the staple economic activity of the sambaqui mound builders and that the idea of evolution from shellfish collecting toward fishing (mainstream up to that point) was fallacious. On the other hand, against a trend to consider mounds as entities isolated in space and time, studies point out the need for systemic and regionally integrated site studies and the fact that shell has been used as construction material for volume accretion at the mound building process. De Masi (1999), using for the first time isotopic analysis in sambaqui studies, has demonstrated that shellfish has no significant contribution in mound builders diet. Finally, studies on fluvial *sambaquis* in the coastal hinterland of the Ribeira valley have shown intensive settling of patchy coastal inland areas by mound builders, a very long-lived occupation (11.5–1.2 kyBP approx.), evoking the presence of coastal mound building societies even before the Holocene sea transgression, dating from the fringe of the Pleistocene (Figuti et al. 2014).

New Perspectives

Around the 1990s begins to appear studies on mound builders lifestyle, technology, diet, health, and behavioral habits (Scheel-Ybert et al. 2009). Bioanthropologists team up with archaeologists and focus on meticulous exhumation of the burials, with attention to depositional and post-depositional patterns and careful recording of the contextual setting, including artifactual and faunal materials. This has led to a much better

understanding of the depositional sequences and mound building processes. The former historical-cultural premises were heavily criticized, the archaeological research on sambaquis has taken a new impulse, and, in this sense, the *Sambaquis & Landscape* project has been paradigmatic, as follows.

The objectives of the studies at the sambaquis from the southern shores of Santa Catarina were twofold. First, understand and describe mound building sequences in terms of site formation processes. As regards this approach, Brazilian researchers have coined the expression "strategic archaeology," referring to the use of previous interventions on the mounds (usually for mining purposes) to access its internal parts and understand the formation processes taking place in their totality, without much additional site intervening (Gaspar et al. 2013). This approach has been successfully applied to Jabuticabeira II (in southern Santa Catarina) and Sernambetiba (Guanabara Bay) shell mounds, among others. Second, explore the perception that these mounds configure dense settlement systems at a regional scope, by using extensive dating vis-à-vis the study of the dynamic coastal physiognomic changes along the Holocene.

The sambaqui Jabuticabeira II was chosen due to the presence of large cavities that have remained from mining, allowing for extensive profiling throughout the mound, complemented by some additional trenching and horizontal exposures. The conspicuous presence of burials associated to specific dark layers related to paleosurfaces of the mound has revealed the funerary architecture of the mound building sequences, reinforced by the absence of domestic activity areas (Fish et al. 2000). Even after 2000 BP, when the depositional regime changes abruptly from thick shell packages to a dark earthen sediment, rich in fish remains and charcoal, the funerary nature of mound accretion remains as the driving vector for mound building (Fish et al. 2000; Villagrán et al. 2010).

On the other side, regional mapping, profiling, and testing have confirmed the existence of a circum-lagunar settlement system, with several large and small contemporaneous mounds, evincing a coeval face-to-face community system sharing, without perceptible discontinuity, the lagoon resources after many a millennia (approx. 6–1.5 kyBP). This approach reinforces the perception (already indicated by the large number of burials in most mounds) that sambaqui societies were sedentary and demographically expressive, thus deviating significantly from previous "small bands of shellfish collectors evolving to fishermen" models (DeBlasis et al. 1998, 2007). The continuous use of the same places for burial purposes, in some cases for more than 2000 years, depicts a strong sense of territorial attachment, a belonging deeply related to the ancestors and strongly tied into their ecologically patchy coastal habitat (Fish et al. 2013).

End of the Opposition Game and a Lot of Questions

It is important to note that these achievements have only been possible with the abandonment of former "theoretical straightjacket" evolutionary schemes, thus allowing for new insights without adhering to established mainstream ideas born in the 1800s that have dominated the scientific scene for most of the twentieth century. Site formation and systemic approaches freed the researchers from "dual thinking," that is, a theoretical structure based on excluding oppositions that prevailed since the beginnings of sambaqui research in Brazil.

First debates focused on whether the mounds were "natural" or "artificial" or its occupants had brachycephalic or dolichocephalic heads, later on, habitational locations or cemeteries, "clean" or "dirty" (i.e., made mostly of shells or earthen sediments), Macaé or Itaipu phase, shellfish collectors or fishermen, bands or macro-bands, simple or complex hunter-gatherers, and this or that. Even if some of these questions might be significant, tagging labels to the sites do not really help on understanding structural aspects of the sambaqui mound builders life and social organization nor help to explain why and how they have built such huge and everlasting mounds, invested so much effort to preserve the bodies of the

deceased and in elaborate funerary rituals to mourn them. Neither help explain how they have created such a successful culture, which has endured, without great deal of change, for so many millennia. This "duality game," so important for the academic research until recently, seems to have got exhausted, because it does not propitiate pertinent insights toward social life, opening space for more contemporaneous and interdisciplinary interests.

For instance, recent studies developed at the sambaquis Jabuticabeira II (SC) and Sernambetiba (RJ) reveal that these mounds have been built upon natural shell beds. Some other shell mounds have incorporated natural sandy layers into their overall volume (DeBlasis et al. 2007). These examples show that the classical opposition "natural × cultural" does not apply, preventing the analysis of the ever-present articulation between the physical environment and the cultural choices of the mound builders.

To move beyond dual thinking and explore the mounds from the perspective of formation processes implied into the mounding sequences have promoted the production of archaeographies in different scales, from burial composition to regional structural recurrences, thus allowing the surpassing of a research agenda defined by pre-existing, tightly framed themes such as "are they collectors or foragers?" This move has brought to the scene new questions, linked to the mound building sequences and processes therein involved. It also promoted the development of new methodologies, freeing the researchers from normative (typological and classificatory) thinking, and stimulating reflection and questioning derived from the characteristics of the archaeological record itself, with an open theoretical mind.

Besides fine-grained sedimentology and zooarchaeology, a wide range of new approaches (analyses of macro- and micro-botanical vestiges, dental calculus, charcoal, the composition of tiny stratigraphic features and post molds into funerary mounding sequences, among others) got together to provide a wide perspective on the sambaqui mound builders' lifeways. On a regional scale, beyond a settlement system approach, comparative explorations on site formation, sediment composition, burial disposition and funerary ritual, mound architecture, health and diet, and so on. These new approaches do not exclude most of the oppositions that based previous research but, building upon them, bring in a whole new perspective, at once anthropological and historical, and strongly related to the evolution of the Quaternary environments on the coast, thus bringing together natural and cultural elements into coastal landscape history.

Emphasis on Recurrence

Fish et al. (2000), in an effort to understand a mound as a whole, have profiled about 340 m of stratigraphic sections throughout the sambaqui Jabuticabeira II. This pioneering approach has detected an amazing recurrence of stratigraphic structuring across the mound, analogue layers, lenses, and burial structures involving postholes, hearths, funerary accompaniments and offerings, and also burial-specific mounding up sequences.

Burials usually concentrate in specific surfaces, perceived as dark layers into the stratigraphic sequences and described as funerary areas. These areas define paleosurfaces of the mound, from where postholes, associated with funerary structures around and over the burials, first appear, plunging vertically through the layers below. The small heaps above the burials are composed by a sequence of lenses with predominance of crushed *Mytilus* shells and fishbone intercalated with tiny dark lenses of sand with plenty of charcoal, ash, burnt fishbone, and plant remains, frequently associated to earths and clusters of fire-cracked rock and artifact fragments (Klökler 2014; Villagrán et al. 2010).

Funerary areas are dispersed all over the mound, frequently overlapping and superposing themselves with clean shell packs in between. These sequences are found all over the mounds and are easily recognizable for the contrasting "clear and dark" visual effect into the profiles (Fig. 4). In the upper "dark earth" package of the mound, when shells almost disappear from the archaeological record, this rationale for mound construction remains the same, even if

Sambaqui Research in Brazil: A Review and Recent Trends (Coastal Archaeology from Southern Shores of Brazil), Fig. 4 Sambaquis profiles highlighting the "clear and dark" contrast

composition changes and fish remains are responsible for most of the materials used in the mounding up process (Klökler 2014).

Sambaqui stratigraphy shows recurrence of such sequences of burial areas with evidence for burial delimiting and fencing, and other paraphernalia, with very much ritualized deposition of bodies and offerings and food remains of feasting. There is also evidence for burning over the burial (apparently after funerary ceremonies are completed) and revisiting (with some interfering and new offerings) for a while after burial ceremonies have taken place. At a certain point, a specific funerary area is closed and covered by fresh layers of clean shell, and the sequence starts all over again, apparently without a significant lapse of abandonment. The recurrence of these sequences toward the centuries has, ultimately, lend the mounds the impressive volume and monumentality that can be seen today.

The realization that the mound accretion is a consequence of the millenary recurrence of specific behavior toward the dead has thrown the study of the burials in to a completely new perspective. The focus shifted from exposing burials and their accompaniments to the understanding of the funerary area as a whole, including its preparation, the ritual deposition of the deceased, the procedures related to mourning and feasting them (and closing the burial place), and the periodic returning to the site (Gaspar et al. 2014). It is important to note that all these behaviors toward the dead are deeply ritualized, and in Santa Catarina they have been kept, with no significant changes, along four millennia at least (DeBlasis et al. 2007; Fish et al. 2013). Findings at the sambaqui Amourins, Rio de Janeiro, for instance, bring unquestionable evidence for the presence of food offerings for the dead. Near the burials were found closed *Lucina* shells with small sections of articulated fish, or a small bone, or even smaller closed shells inside, like a delicate and valuable container, or package, for the food offered to the dead (Gaspar et al. 2013).

Daniela Klökler's zooarchaeological and site formation studies (2014) have brought some detail into these rituals involving death and food. Analyzing samples from different parts of Jabuticabeira II, she has identified distinct behaviors related with faunal materials, appearing sometimes as a whole fish skeleton or mammal parts and sometimes as dispersed and/or burnt assemblages of fishbone, in different layers. This detailed analysis has brought light into the carefully organized funerary rites, involving selection of species in offerings and using massive amounts of fish for feasting. By or above the burials, whole fish skeletons or whole bird or mammal parts have been found, well preserved and without cutting or burning marks, taken as evidence for offerings deposited together with the deceased.

In contrast, most of the mounding up over the burials is composed of common and abundant lagoon fish species like the croaker (*Micropogonias furnieri*) and catfish (*Genidens barbus* and *Genidens genidens*), and the predominance of small individuals suggests net fishing. Larger prey, occasionally present as offering, is rare in the feasting remains deposited over the burial. The absence of large fires suggests that feasting takes place nearby, and the remains are brought to the funerary space and deposited over the burial. This interpretation is reinforced by the low degree of shell fragmentation into the mound, suggesting little circulation into the funerary area (Villagrán et al. 2010). After feasting and covering the burial, large fires were lit above and nearby, but its composition does not seem to be related to food preparing and feasting. These ritual

fires on the top of the mound would propitiate the closing of the burial and would be visible from far, announcing the end of a mourning cycle.

The economic basis of the sambaqui society subsistence, that earlier has given support to the evolutionary line "shellfish collectors to fishermen foragers," has also known new contributions. Initially, demonstrating that fishing has always been the staple economic activity and that shellfish collecting, although impressive in mound stratigraphy, has never been a staple resource. Moreover, recent studies on dental calculus, anthracology, and micro-vestiges into sediments have pointed out the importance of plant foods on mound builders' diet (Scheel-Ybert et al. 2009). These studies demonstrate that the nutritional spectrum of the sambaqui people go well beyond the faunal profile seen by naked eye on mound stratigraphy.

Recent studies with lithic industries from Jabuticabeira II and other southern mounds reveal a very interesting technological profile, far from the "primitive" picture drawn before. Although production sequences are relatively short, there are a variety of flaked scrapers and piercers and a great deal of sophistication in choosing and polishing the supporting pebbles for axes and zooliths, with very precise carving tools produced by splitting slabs of basalt. Moreover, a number of different types and sizes of grinding stones and pestles reinforce the notion of the importance of vegetable food in everyday diet.

Another interesting insight comes out from Klokler's (2014) analysis of carbon and nitrogen isotopes of 14 individuals from Jabuticabeira II. It shows that mound builders' diet was based on fish from high trophic levels and sea and land mammals, thus in sharp contrast with the zooarchaeological record on mounding stratigraphy. This contrast supports the idea that intensive fish consumption relates to feasting, while everyday meals would have stronger sea (whale, shark, and ray bones are frequently found associated to burials) and terrestrial game components and taken place mostly outside the mound. Croakers and catfishes, easy to catch in large quantities into the lagoon, would be prone to provide for the commensality inherent to funerary ritual, suggesting it to be an integrative social event, promoting solidarity and reciprocity and creating or reinforcing allegiances among communities.

This study reinforces former interpretations, on the northern coast of Rio de Janeiro (Gaspar et al. 2013) and on the southern shores of Santa Catarina (DeBlasis et al. 2007), based on site distribution and chronological concomitance, pointing out that mound builders communities show a high level of regional integration and collaborative behavior. Additionally, evidence for violent death seems uncommon among mound builders (Lessa and Medeiros 2001).

The commensality detected among sambaqui societies is recurrent among South American native groups ethnographically described, a cultural trace that seems to pervade many cultures and displaying a long history. Besides, the use of shells for mound building must not be underestimated. The microenvironmental conditions created by massive amounts of shell have propitiated the preservation of the burials, quite often in very good conditions. It is unlikely that it has not been intentional; it seems that the sambaqui people valued the body and made a great effort to preserve it even after death.

The study of the burials went well beyond the analysis of the skeletons themselves, expanding to the processes involved in disposing the bodies. The archaeological remains of the disposing of only one body, considering the complete ritual performance and features involved, occupy more than 2 m^3. In its recurrence throughout the sambaqui, it is paramount to understanding the organization of space and site accretion processes, in other words, its architecture (Bianchini 2015). Gaspar et al. (2013) point out that sambaqui culture is very careful with the bodies, investing time and effort to keep the memory of the deceased, and, as regards mound building, they occupy a central place (Fish et al. 2000). From this perspective, the evidence from the excavations at the sambaquis Sernambetiba and Amourins, Rio de Janeiro (Heredia et al. 1982), has been reassessed. The examination of the field notes has allowed detecting artifact clustering in some levels,

always associated to funerary heaping, as if these structures acted like attraction elements to artifacts and fire pits.

Another focus of research is the understanding of different depositional processes. Zooarchaeological studies developed on different sambaquis from Santa Catarina have been able to define different activities and occupation patterns along the stratigraphic sequence, some performed in situ and some others made of materials redeposited from elsewhere. By means of micromorphological analysis of sediments from Jab II, Villagrán et al. (2010) make clear distinction between primary deposits, such as body deposition and the *mise-en-place* of funerary accompaniments and fires, and secondary deposits, mostly related to the mounding up processes from feasting remains and others brought in from outside areas. This perception led to the need of exploring activity areas outside the mound, revealing peripheral small structures undoubtedly related to the events taking place in mound building.

Anthracological studies by Scheel-Ybert et al. (2003) indicate that wood used for cooking and funerary fires was obtained in the surroundings, mostly dead wood and *butiá* (palm) seeds, while the wood used for constructing fences and funerary structures has come from further away, probably from nearby mountain forests.

Villagrán (2014), examining several mounds at the southern shores of Santa Catarina, compares their stratigraphic sequences, concluding that the complex formation sequences of the sambaquis can be reduced at least one main action: the recurrent redeposition of midden material possibly carried in from domestic spaces. Recognizing that sambaquis are artifacts of long-term production, she concludes that the thick and apparently complex stratigraphy seems to be made after the recurrent deposition of similar contents and depositional behaviors.

Bianchini (2015) explores the depositional architecture of the Sernambetiba mound, taking advance of the scars left by excavations from the 1970s and 1980s, plus some additional trenching. This relatively late shell mound (2.3–1.5 kyBP) has an internal structuring and geometry of the stratigraphy, such as mounding structures, flat shell surfaces, dark and ashy lenses, posthole distributions, the burials themselves, and the geological substrate. Characteristic features are the "visiting structures," that is, encircling deposits that affect laterally the surrounding layers. The lateral contact of these features is usually abrupt, and composition does not differ from other layers; nevertheless, the organization of the shell materials is chaotic and is mostly associated to burials aside or above. They have been interpreted as successive interventions into the burial scene, deconstructions and reconstructions, apparently due to the manipulation of older burials when bringing new ones to the mound.

Klökler (2014), Gaspar et al. (2013), and Villagrán et al. (2010) have already pointed out the existence of these features, but Bianchini (2015) carefully describes, at Sernambetiba, a secondary burial in a small basket intervening in former burials. At that same site, careful examination of the burials, and the places where they have been deposited, has revealed intense activity in the funerary areas. Secondary burials exhibit cutting and burning marks, evidence for manipulation, reinforced by chronological inversions of dated burials in stratigraphy.

The careful analysis of the depositional architecture also comes in supporting the perception that the funerary areas have been intensely remodeled and older bones into later sediments are to be occasionally expected. Chronological inversions occur not only in the funerary areas but also in the covering heaping sequences above them. As suggested by Bianchini (2015), funerary mound building is deeply related to the alive, reflecting active roles in the social context. It changes with time, vanishes from memory, and needs to be continuously refurnished, reconfigured, and reenacted. As regards the sambaquis case, the detailed analysis of depositional architecture reveals that the building process includes "demolition," redepositing, and refurbishing, and not just accretion. Moreover, studies by Klökler (2014) have suggested that the funerary mounds are organized social facilities, with areas for circulating, open spaces and areas where circulation is restricted.

In her detailed study at Sernambetiba, Bianchini (2015) reports well-preserved tiny and fragile mussel deposits alternating with ashy lenses into the burial heaps, an evidence for a reserved place, not subject to circulation, walking and/or trampling. These fires and deposits are probably related to ritual activities, as suggested by their immediate relation to the body deposited below the heap; thus it sounds pretty reasonable that the whole burial structure are not an area for free circulation, at least while memory of the deceased person remains alive. The heaping up structure itself imposes a limit, as well as eventual fences and other wooden tomb structures.

At the same time, burial heaps relate laterally to flat surfaces of packed shell, sometimes extending up to 10 m, constituting large platforms that, eventually, can be detected along the profiles. Their flat and extensive geometry and the way they relate to the burial mounds indicate that they were paved areas right below and around the burials, probably for circulation, as no burials have been found into them. It is likely that at these open surfaces, and circulation areas, possibly are where ritual performances have taken place.

The recurrence of stratigraphic sequences and related features in different mounds, detected by means of different research strategies and different researchers, reinforces that sambaquis are, essentially, ritual activity locations. Ritual activities are traditional and defined by formality, invariance, and performance, among other characteristic behaviors, and are an aspect of social life less susceptible to changes and adjustments; after van Gennep (1960 [1909]), rites are exceptional situations but always relate, somehow, to everyday life. Formal reenacting performances are their principal characteristics, while routine activities allow for behavior that is more flexible, especially in terms of space and time. At the sambaquis, the large amount of burials and the abundant evidence as regards mound architecture speak aloud toward its nature as the *locus* of funerary ritual, a space related to the dead and full of symbolic connotations.

Regional Facies and Social Change

The study of social change has taken new directions after the 1990s, particularly due to the intense cross-interdisciplinary referencing of contemporaneous research, involving up-to-date analytic methodologies and techniques (e.g., isotopic analysis) and regional approaches. Long-term research projects propitiate rigorous chronological control and access for a variety of different and complementary approaches teaming different specialists (anthracology, zooarchaeology, geoarchaeology, geophysics, DNA, etc.), thus producing more robust hypotheses and interpretations.

In Santa Catarina, one indicator of change is the shift from shells to fishbone as principal building material (Fish et al. 2000; Villagrán et al. 2010). This change, very neat in the stratigraphy, might relate to changes in symbolic aspects of the funerary program but might as well reflect environmental changes taking place in the lagoon around 2000 years ago. The appearance of pottery associated to inland Je-speaking groups, some 600 years after, is also a sign of change and intercultural contacts; nevertheless, bioarchaeological studies by Okumura and Eggers (2014) point out the continuity of biological affinities and the growth of violent death among coastal populations. The isotopic analysis by Colonese et al. (2014) also reinforces the continuity of subsistence practices, while Hubbe et al. (2009) suggest changes in the postmarital residence practices. Moreover, isotopic analyses by Bastos et al. (2011) reinforce the perception of a considerable amount of endogamy and regional pooling among these mound building groups dispersed along the coast. Even if they do have contacts and exchange, people seems very much attached to their local networks. In this sense, Hubbe et al. (2009), using epigenetic traces of the skeletons, have suggested the existence of microevolutionary contexts, and Okumura and Eggers (2014) point out the evidence for biological affinity between older shell mounds and later dark earthen/fishbone-borne structures, whether with ceramics or not, implying a great deal of regional cultural continuity.

Indeed, there is a peculiar rock art tradition in this area, with typical geometric engravings and clusters of polishing basins on coastal diabase dykes at prominent coastal rocky shores. Although geometric compositions predominate, evoking, sometimes, fantastic entities, sketchy human figurines also appear. These representations share a common esthetic grammar, and their distribution along the coast/island system of the central shores of Santa Catarina reinforces the idea that this art style is related to the peculiar cultural scene that emerged into this area during the recent Holocene (2500–800 BP approx.).

Regional Diversity and Structural Consistence

Since the anthropogenic nature of the sambaquis became clear, archaeologists have focused on mapping evolutionary change through the variability of the archaeological record, taking into consideration stratigraphic, faunal, and artifactual changes to discuss adaptation, diet, economic changes, and intensification, among other issues (Gaspar et al. 2008).

The mounding nature and longevity of the sites have propitiated intra-site comparisons, even if, in most cases, only a tiny portion of the whole site has been examined. From this kind of analysis, it has emerged evolutionary interpretations of the economic and social changes of the sambaqui culture, such as the transition from a shellfish collecting way of life toward fishing intensification. Changes in the relative amount of faunal materials were taken as direct evidence for dietary preferences, regardless their structuring toward the distribution of features like fires, burials, and the mounding up processes involved therein. The presence of potsherds into the upper layers of the mounds reinforced this evolutionary perspective, referencing the arrival of foreign ceramist Je- and Tupi-speaking societies occupying the top of the mounds and the adoption of agriculture.

One of the authors of the entry thinks that it is unlikely that these late-coming agriculturalists might have simply given away their former cultural habits as they arrived at the coast and that these sherds rather reflect cultural contacts and exchange. At least in some areas, like the central coast of Santa Catarina and the Lakes Region in Rio de Janeiro, these intercultural relations with Je groups seem to have given rise to new cultural expressions (Barbosa-Guimarães 2007). "Pure" Je sites, as well as Tupinamba settlements, are located at the more interior sections of the lagoon area, where their funerary traditions, strongly different from the sambaqui culture, have been kept. In Rio, as well as in Santa Catarina, the contacts with Je societies seem to have been slow and fluid, and the sambaqui people seem to have preserved most of their habits for about six or seven centuries after the first contacts.

Around the Guanabara Bay, Sernambetiba seems to be at the end of the shell mound building era, right before, or even contemporaneous, to the Tupi-speaking groups' arrival to the coast. In this sense, the peculiar body treatment given to the dead at this site might be related to this dramatic moment of conquest and cultural disruption. However, even being a late site, Sernambetiba is pretty large, revealing that, at the fringe of its disappearance, the sambaqui culture in this area was still strong and attached to its old traditions.

In the northern coast of Santa Catarina, the presence of Je-style potsherds in the upper layers of the Forte Marechal Luz shell mound without further noticeable cultural changes has led Bryan (1993) to suppose the presence of Je women among the sambaqui people, thus evoking cultural and biological exchange. Throughout the Brazilian coast, sambaqui mound builders have shared similar cultural rules toward the dead and very similar architectural and ritualistic principles as regards mound building processes. The demographic expansion and economic intensification of the sambaqui societies seem to have been even more intense toward the southern shores, where at least for 6000 years, sambaqui people have been continuously building the enduring monumental mounds we can still see today.

In the northern shores of Brazil, a different and less studied scenario brings new tonalities to this discussion. Shell mounds over there are slightly older (around 6 kyBP), and ceramics appear throughout the mounding sequence, a distinctive

small, sand, and shell-tempered ware almost without decoration. Reexamining these materials at one of the excavated sites of the area, Lopes (2016) confirms the widespread distribution of these sherds into the stratigraphy of the mound. Nevertheless, he observes that potsherds are too small (less than 5 cm) and are difficult to refit and seem to have entered the mound as secondary deposition. And, very important, he has detected several burials, with mounding up processes upon them, associated fires and other evidence that make these northern mounds structurally similar to the southern ones, sharing with them the same building rationale, thus also sharing the same cultural and ideological background.

Despite the fascination exerted upon archaeologists by social evolutionary thinking, it is not an easy task to explain changes detected in the material expression of the sambaqui way of life. Linear readings of the archaeological record have shown their fragility, and its interpretation demands a more comprehensive contextual approach, tuned on both regional variability and long timeframe scales. Faunal variability must be understood as regards the Holocene coastal dynamics at a regional scale and demands the adoption of a zooarchaeological methodological framework allowing for adequate nutritional input, as well as seasonal fluctuations. Sometimes an apparently abrupt disruption in the stratigraphic record, as has been detected at Jabuticabeira II (Fish et al. 2000; Villagrán et al. 2010), when looked at more attentively, reveals a great deal of continuity in faunal proportions, layer-sequence structuring, and the presence of distinctive features such as burials, postholes, and hearths.

The funerary nature of the mounds throughout the long period of the sambaqui occupation is taken here as a central expression of the sambaqui society cosmogony, and, in this sense, integral to its cultural essence, the millenary continuity of this culture strongly comes out. Funerary ritual, episodic in nature, acts as passage rite (van Gennep 1960 [1909]) mobilizing, integrating, and reordering all the members of society (particularly as regards the so-called "simple" ones) and, usually, assumes rather peculiar and exclusive aspects. It is deeply related to cosmogony and, although not intrinsically connected to environmental transformations, sometimes reflects them in some way. This perspective seems to be the most adequate to approach the study of the sambaquis, given the large amount of burials found at these sites and the fact that they seem to be the reason behind mound building.

Gaspar et al. (2008) suggests that, for sambaqui society, the dead has fundamental importance and their locale occupies a special and distinctive positioning into the landscape, where funerary ritual takes place and its essence is to preserve, transform, and control the body. The vital importance of the body as cosmological principle is, by no means, exclusive of the sambaqui society but a cultural characteristic widely acknowledged among South American native societies. After Viveiros de Castro (2002: 388), the emphasis in the social construction of the body is a differential of the Amerindian cosmologies.

Let us have a look at the body treatment reported in the Lakes Region, Rio de Janeiro. Estanek (2016) relates, at Sernambetiba, tight wrapping and defleshing in 17 burials, while other have been manipulated and redeposited (secondary burials), a process involving intentional bone selection and fragmentation, reburying in small baskets (or something similar) and parts preserved in connection, such as hands and feet. Furthermore, sections of the vertebral column and members (both inferior and superior) have been disconnected and regrouped with other parts and the crania intentionally broken and deposited together with the rest, thus giving to the burial a more compact outcome. Estanek stresses the intention of modifying the original design of the body, and, even at the primary burials, the hyperflexion of the members is extreme, in order to make them acquire rather unusual positioning. In addition, although never cremated, almost all skeletons are slightly burned or show evidence of intense heating, probably due to proximity to fires lit during the mourning period or even after that. A bit further to the north, at Corondó (4.2–3 kyBP), bone manipulation has also been reported. Machado (1995) retrieved collars of human teeth over the skull of children, and, at Saquarema (3.3–2.5 kyBP), long bones display cut marks and the sectioning of the epiphyses, probably after defleshing.

Manipulation of human skeletons has been noticed in sambaquis all along the Brazilian coast, particularly as regards secondary burials, although body manipulation seems to be particularly intense at the Lakes area. For instance, Okumura and Eggers (2014: 109) have analyzed 89 individuals from Jabuticabeira II, and only 1 small star-shaped cut marks have been found. Although anatomical rearrangements are the most common intervening, there are also tight-flexed primary inhumation, indicative pre-burial body manipulation, and/or active defleshing, repositioning of long bones and the incorporation of some (older) bones into new burials.

Other interesting feature of the funerary treatment at the sambaquis is the use of reddish ocher over the burials. Although a widespread practice along the coast, it seems to have been especially intense in the Lakes Region, at the sambaquis Beirada, Moa, Pontinha (Kneip and Machado 1992: 32), and Manitoba (Machado 2001), where a large amount of colorant has been applied over some funerary structures. Cremation has also been reported at the older layers of the sambaqui of Pontinha (among other sites) around 2.3 kyBP, while, at the upper layers (1.8 kyBP), the burials are primary. Barbosa-Guimarães (2007) suggests that cremation is related to contacts with Je-speaking peoples arriving to the coast, a phenomenon also recurrent in the southern shores, with analogous explanation (DeBlasis et al. 2014). Indeed, it is clear that the arrival of these hinterland Je groups to the coast is somewhat related to the collapse of the long-lived sambaqui tradition all along the central and Southern Brazilian coast, while, at the northern shores, these cultural sequences are still poorly known.

Thus, as Lilia Machado (1995) has pointed out, after examining 445 individuals from Corondó and 75 from Malhada, despite some variability in the individual treatment of the body, it is perceptible that the whole funerary program is rather traditional, displaying an amazing continuity through time and place. We feel comfortable to expand this perception to the entire Brazilian coastal area, adding that ceremonial performance involves a mounding up rationale, intense use of fire, and conspicuous accretion of food remains resulting from feasting.

Innumerable factors might be influencing individual variability as regards funerary peculiarities. Personal abilities and powers, marriage and social inception, life and death circumstances, parental affiliation, even regional fashioning of a certain time – conjuncture events important enough to be remembered, or evoked, in funerary rites. As already pointed out, it is in body treatment that social difference emerges in Amerindian societies (Viveiros de Castro 2002: 387–388), and that is probably why there are so many tiny differences among sambaqui funerary structures. For that reason, as well, understanding what lies subjacent to all this variability, the structural rules that are essential to the sambaqui social organization and perception of the world are the principal defiance ahead for archaeologists today.

There is an apparent paradox in the perception of a cultural pattern that has remained stable for about 6000 years, without significant change, while settlement longevity and demographic markers point out toward a considerable intensification in economic productivity. Mound building, on faunal (and other) materials, of a ritual space for manipulating and preserving the dead and the presence of ocher, adornments, and offerings, all with deep symbolic meaning, seem to indicate a society where the cult of the ancestors is among the most important structuring elements, a cultural trace that integrates all sambaqui communities of a region. And, as the use of zooliths suggest, also connects a sequence of social aggregates along the linear coastal shores, thus generating macro-regional spheres of interaction that, despite local differences, bring out an amazing structural homogeneity all along the Atlantic shores.

Sambaquis Shell Mounds, Archaeology of

Maria Dulce Gaspar
Departamento de Antropologia,
MUSEU NACIONAL / UFRJ, Rio de Janeiro, Brazil

Introduction

The Brazilian coast was settled by groups of fisher-gatherers who built mounds known as sambaquis. These mounds (Fig. 1) are the main archaeological evidence of these groups, known as sambaquieiros or shell mound people. Sambaqui is a word of Tupi etymology, the language spoken by farmers and ceramic-making groups that occupied the Brazilian territory when Europeans arrived. Tamba means shell, and ki means mound, which are the most important visual features of these sites.

The oldest dates indicate that some areas of the coast were already occupied around 7000 years ago and the territory was intensively populated by mound-building groups between 4 and 3000 years BP. These fisher-gatherers dominated the Brazilian coast until 2000 BP, when ceramic-making groups originating from central South America and Amazonia began to occupy coastal areas and destabilized the sambaquieiros' way of life.

Definition

Sambaquis are typically characterized by rounded, elevated structures in southern Brazil; some sites reached 65 m in height, although the sites are usually not higher than 5 m in other areas.

Sambaquis Shell Mounds, Archaeology of, Fig. 1 Santa Marta Sambaqui, Santa Catarina, Brazil

The archaeological deposits that compose these sites primarily include mollusk shells and bones of fish, birds, and mammals. A variety of stone and bone artifacts, postholes, and hearths have also been identified, often resulting in an intricate stratigraphic record. The most noticeable remains in the composition of these sites are the shells from *Anomalocardia brasiliana*, *Lucina pectinata*, and several mussel species. Burials of men, women, and children of different ages have been recovered from the most sambaquis, and the skeletons are usually articulated. These sites are a distinct space that becomes conspicuous on the landscape because of their sheer volume and the topographic nature of the coastal plain. They served as the final destination of the deceased, particular places, in which concentration of shells neutralized soil acidity and created conditions conducive to the preservation of human bone.

The prehistoric occupation of the Brazilian coast caught the attention of researchers long ago, and scientific interest in this type of archaeological site has been significant since the second half of the nineteenth century. Initially, the issue that dominated the studies concerned natural versus anthropic origins of the sites. The "naturalist" school argued that sambaquis were the result of receding sea levels and the resulting effects of wind upon shells on the beach. The presence of human remains was commonly attributed to shipwrecks. In contrast, scientists that believed in an anthropogenic origin asserted that the sites were the results of human action and proposed multiple explanations for the accumulations of faunal remains.

The advancement of research at several sites and findings of indisputable evidence of human activities made the naturalistic movement lose its followers. However, the origins of sambaquis were discussed until the 1940s by some researchers who argued that the sites were created by a combination of natural and anthropic elements. This perspective became known as the "mixed" theory.

Since the nineteenth century, the proponents of anthropogenic origins of sambaquis are divided among two distinct views that continue to influence current research. On one hand, sambaquis are considered to be the results of casual accumulation of food refuse because of the large quantity of faunal remains found at the sites. The other perspective argues that the sites are mortuary monuments because of the presence of burials (Wiener 1876). These distinct perspectives

emphasize different functions of the settlements: the first model suggests that sambaquis were habitation sites, while the second supposes that they were cemeteries.

Although the focus of early debate was the origins of sambaqui formation, some important contributions were made at the end of the nineteenth century, including observations about formation processes, landscape, composition, chronology, subsistence, and the physical characteristics of the populations. Some of these topics remain current and more fully developed, while others have been dismissed. One of the main issues that dominated the social sciences in Brazil between the end of the Empire and the First World War (1889–1914) was the diversity of the human species and the notion of race, later rejected as a scientific category. Skeletons, especially skulls, were favored by researchers, often to the detriment of other materials, and they were used extensively in the first works of Brazilian anthropology, dating from 1860. These studies were influenced of French and German authors and were strongly affected by deterministic, racial theories (Seyferth 1985). These investigations resulted in extremely descriptive research, focused on characterizing human "types."

Although eventually dismissed, the naturalistic theory resulted in an important contribution to the understanding of sambaquis. Some researchers explored the idea that rather than being the result of natural forces, sambaquis mark natural processes, and they can be good indicators of sea-level variation. For example, Krone (1908) believed that older sambaquis, composed predominantly by oysters, were farther away from the modern coast, while more recent sites would be located close to the sea and composed of *A. brasiliana* shells. These studies were significantly developed from the 1970s onward with research focused on comprehending coastal evolution.

Some geomorphologists, considering that the basis of sambaquieiros' diet came from the sea, believed that the groups lived closed to the coastline. For these researchers, a site's spatial proximity to the sea was used to make inferences about coastal dynamics (Martin and Suguio 1976). Despite being considered questionable evidence for some (Scheel-Ybert et al. 2009a), spatial distribution research yielded important results. Recent coastal evolution analyses resulted in indispensable paleoenvironmental reconstructions, allowing the characterization of locales chosen by sambaquieiros to erect their settlements, as well as an understanding of the criteria that guided site selection.

Until the 1950s, sambaqui studies were focused on individual sites, hindering the broader understanding of coastal occupation. In this same decade, the first systematic works were completed, and radiocarbon dates were recovered. French and North American archaeologists, including Annette and Joseph Emperaire, Alan Bryan, and Wesley Hurt, went to Brazil to study two eminent topics of the country's archaeology: monumental sambaquis and the hunter-gatherers of Lagoa Santa, Minas Gerais. At the same time, Brazilian intellectuals, led by Castro Faria, Paulo Duarte, and Loureiro Fernandes, initiated an intense movement aimed at the protection of the sambaquis, which had been continuously destructed for large-scale lime production since the sixteenth century.

Slowly, the number of studied sites increased, along with the breadth of the research questions being addressed. The noteworthy accumulation of knowledge that occurred from 1965 helped to renew the discipline. Two large projects had great repercussions in the way archaeology was carried out in Brazil, leaving strong impressions upon the predominant theoretical and methodological perspectives among Brazilian archaeologists: the National Program for Archaeological Research (PRONAPA) was initiated in 1965 and coordinated by Clifford Evans and Betty Meggers, while the French-Brazilian Mission was created in 1973 and coordinated by Annette Laming-Emperaire.

The major concern of Brazilian archaeology until the end of the 1980s had been the investigation on cultural change through time. The discipline was marked by the creation of various phases and traditions used to define economic transformations deemed important. This system prevailed for more than two decades; the site-

based approach and the interpretative scheme became practically synonymous with archaeology in the country. Conversely, some isolated studies started to investigate the spatial organization of sambaquis' internal features. The distribution of hearths, house outlines, and burials were studied using teachings from French archaeology to understand their complex arrangement (Kneip 1976). One notable exception is Prous (1974), who detected great similarities in the representations of animals in bone and lithic sculptures and suggested the possibility of some form of ideological unity shared by sambaquieiros from the southern and southeastern coasts.

Scholars who considered sambaquis as deposits of food refuse were particularly interested in investigating faunal remains. At first, this line of research focused exclusively on the identification of animal remains, resulting in long species lists. Later, the lists were supplemented by quantification of the identified elements, and researchers tried to infer the dominant economic activities. Finally, bones and shells were counted, and correlations were made between the remains and the quantity of food they represented. This was a significant advancement, as the visual prominence of the shells was overcome. Shell valves tend to preserve well in the archaeological matrix and are obviously notable because of their color and volume. These characteristics give the impression that collection of shellfish was the primary activity that sustained the population. The goal of investigators was to characterize the diet, treating the sites individually without advancing in the delineation of social relationships of an economy based on aquatic resources.

Systematic studies of food remains were linked to PRONAPA's perspective, and this context helped to elaborate a reference model that persisted until the beginning of the 1990s. The model asserted that the sites' different layers were the remains of successive settlement episodes by bands of nomadic gatherers and mollusks were the basis of the diet. Environmental alterations related to sea-level changes and/or mollusk bed overexploitation were believed to have led the sambaquieiros builders to change their economic basis, transforming them into fishers. The location of the sites in relation to the coast was frequently cited as evidence in support of this hypothesis.

The 1990s brought renewed interest in sambaquis, and the representation of these groups changed. They were no longer perceived as bands of nomadic mollusk gatherers searching for food. Researchers began to discuss social organization, site formation processes, and the elaborate funerary ritual, and the grandeur of the sites was now seen as the outcome of more complex social interactions. The paradigm was forever changed, usurping the preconceived notions that had lingered since the nineteenth century, equating the sambaquieiros to "primitive" people.

Key Issues/Current Debates/Future Directions

Recently, archaeologists have pursued the idea that sambaquis themselves are artifacts, constructed according to social rules making it possible to study not only their content but also their form, function, and settlement implications. As a consequence of their visibility in the coastal plain environments, sambaquis are considered landscape markers, further transforming approaches to this type of site.

In the first decade of the twenty-first century, different scales of observation were articulated to build interpretations about the lifeways of sambaquieiros. On one extreme, a broad perspective investigates satellite images to study site distribution and function and settlement patterns. On the opposite end, some scholars use a focused approach, employing microscopes to examine evidence like dental calculus, joint conditions, and wood fragments, providing information about some of the more particular habits of coastal groups.

Research focusing on groups of sites attempts to understand the relationships among the units and their characteristics. Since sambaquis have different dimensions, the hierarchical relationships among settlements are discussed, and since many neighboring sites were simultaneously occupied, scholars also explore their

complementary roles. It has been argued that isolated sites did not have sociological significance and that a set of sambaquis is the minimum unit of occupation. It has also been established that sambaquis occur in all regions of the Brazilian coast and are concentrated in areas where the coast is interrupted by rivers, estuaries, and lagoons. Some scholars argue that, despite regional and temporal specificities, sambaqui builders had a "collective individuality," in the sense proposed by Marcel Mauss (1979). Comparison with other types of sites located in Brazil indicates that the custom of building mounds in the coastal plain through accumulation of faunal materials and interring the dead in these spaces is a custom exclusive to the sambaqui population.

Systematic studies interested in landscape use and the spatial distribution of sambaquis use an approach that involves detailed knowledge of coastal evolution, site dimensions, site function, and formation processes. Research at Santa Marta paleolagoon, in Santa Catarina state, confirmed an ample territorial overlapping, as in other areas, clearly indicating patterns of community interaction surrounding the lagoon. Lagoons were the epicenter of these groups' social and economic universe. The spatial configuration of sites, along with the analysis of several radiocarbon dates, demonstrates that some sambaquis were active for more than eight centuries. Analysis of the visibility of large sites, almost always central within each site cluster, indicates the existence of sedentary communities that grew in the surroundings of the lagoon (DeBlasis et al. 2007). Demographic parameters suggest impressive concentration of people in some areas of the Brazilian coast (Fish et al. 2000).

A fundamental interpretive change occurred regarding sambaquis' formation processes: faunal remains cease to be seen solely as indicators of diet but also as building materials. These changes refer specifically to the shells, since isotopic studies indicate mollusks did not make a significant contribution to the diet of sambaquieiros (De Masi 1999; Klokler 2008). In fact, new zooarchaeological methods and analyses demonstrate that fishing was always an important subsistence activity of these coastal groups (Figuti 1993). Moreover, paleobotanical studies and analyses of plant remains recovered from dental calculus and lithic artifacts show a more diverse diet than previously thought. The diet included a great variety of wild plants, and probably some cultivated species as well, which possibly included some

Sambaquis Shell Mounds, Archaeology of, Fig. 2 Jabuticabeira II Sambaqui, Santa Catarina, Brazil

cariogenic species. An incipient form of tending and harvesting (horticulture) of tubers and fruit trees is suggested in many sites located in the southeastern region and at least in some sites of the Brazilian south (Scheel-Ybert et al. 2009b).

Concerning the funerary realm, sambaquieiros' use of mollusk valves to build their cemeteries assured the preservation of human skeletons. This preservation, associated with the visibility of the dead, who controlled the sambaquieiros' territory from the top of the sites, resulted in a particular funerary program. Everything within a sambaqui seems to have followed the logic of increasing the height of the monument while at the same time guaranteeing better visibility for the dead.

Studies of several meters of profiles from the site Jabuticabeira II, in Santa Catarina (Fig. 2), indicate that its volume, 320,000 cubic meters, is primarily a consequence of activities related to funerary ritual. The ritual involved the deposition of the body in the top of the mound, inclusion of large quantities of offerings, and long-term maintenance of hearths, resulting in thick deposits of ash.

Hyperflexed bodies were deposited close to each other, delineating funerary areas within the large site. Shallow graves were delimited by posts, occasionally made with hardwood (Bianchini et al. 2007). After the deposition of many burials, the areas were closed with the deposition of successive lenses composed predominantly by shells or fish bones, charcoal, and sand, resulting in an intricate stratigraphic sequence (Fish et al. 2000; Klokler 2008).

Studies of archaeofacies propose that the materials were processed in spaces outside the site and had different treatments before being deposited within the sambaqui. In this way, the body and its associated offerings comprise a primary deposit, and the materials covering the funerary areas were secondary or tertiary deposits. The materials that cover the funerary areas may have been accumulated in small sambaquis located nearby, whose archaeological layers rarely surpass 40 cm in thickness (Villagran et al. 2010).

The repetition of funerary ceremonies throughout more than eight centuries created a monumental element in the landscape that, due to its size and configuration, perpetuates a message that its builders wanted to transmit (Fish et al. 2000). The successive events, directly related to the process of site growth, inform visitors to the coast that the area is the sambaquieiros' domain where they interred their dead. In this way, sambaquis are the result of intense social processes that resulted in a highly domesticated landscape, marked by sentimental and emotional references.

Sanders, William T.

Charles C. Kolb
Division of Preservation and Access, National Endowment for the Humanities, Washington, DC, USA

Basic Bibliographic Information

William Timothy Sanders (April 19, 1926–July 2, 2008), a dedicated anthropological archaeologist, charismatic scholar of New World archaeology, innovative investigator, highly influential theoretician, popular and dynamic teacher, and prolific author, enjoyed an international reputation and changed the course of Mesoamerican archaeology in the 1960s. Born and raised in Patchogue, Long Island, New York, he served in the US Navy during World War II as a PBY air crewman on Mediterranean Axis submarine patrol based in North Africa. Accepted as a student at Harvard College under the GI Bill (Servicemen's Readjustment Act of 1944), he was awarded an AB magna cum laude in anthropology, elected to Phi Beta Kappa, and received his AM (1953) and doctorate (1957) from Harvard University. Archaeologist Louis Dupree was a friend and fellow student. Sanders' 700-page dissertation, *Tierra y agua (soil and water)*, formed a basis for subsequent fieldwork in lowland and highland Mexico, Guatemala, Honduras, and Peru. In 1960 he initiated the pathbreaking Teotihuacan Valley Project, an archaeological settlement pattern assessment covering 610 km^2 (Sanders 1965; Sanders et al. [12 volumes] 1970–2007; Kolb 2019) leading to the larger Basin of Mexico Project analyzing an area of 7500 km^2 occupied by a growing Mexico City. The result was a monumental book – now a classic – and detailed maps documenting the evolution of civilizations and empires (Sanders et al. 1979). The highland Maya Classic period city of Kaminaljuyú (encroached upon by modern Guatemala City) and surrounding Valley of Guatemala, ca.700 km^2, was the focus of a 5-year (1968–1971) endeavor by Sanders and Joseph Michels to survey and conduct excavations (Sanders and Michels 1977). By invitation of the Honduran government, Sanders and David Webster focused next on the 460 km^2 Copán Valley in western Honduras (1981–1985) to reconstruct the social, political, and economic institutions of the city of Copán at its ca. CE 700–800 peak (Sanders 1986–1990).

Charles C. Kolb has retired.

S

Major Accomplishments

Sanders was among the first archaeologists to attempt to make the discipline of archaeology a true science through the development of theories and the formation of testable hypotheses about culture (Marcus 2011). His approach, cultural ecology, provided fundamental environmental and archaeological data to assess the evolution of ancient societies. He shifted the scale of analysis from individual sites to the macroregion to document population growth and dispersal and identify processes leading to urbanization and civilization. The fieldwork utilized aerial photographs as a guide to site location and full-coverage survey, a technique used widely today, along with student crews for on-foot site verification. Sanders created an extensive corpus of empirical data, including the location of thousands of archaeological sites (many since destroyed by modern urban growth) and the environmental settings in which they arose.

He was the author, coauthor, or editor of 25 books, major reports or monographs, numerous book chapters, and professional papers published in English and Spanish. A great synthesizer, he coauthored with Barbara Price *Mesoamerica: The Evolution of a Civilization* (1968) and, with Joseph Marino, the textbook *New World Prehistory: Archaeology of the American Indian* (1970). Sanders was a frequent commentator at professional meetings and instrumental, with Frederick Matson and Louis Dupree, in establishing the separate Penn State Department of Anthropology in 1965. He created and narrated the 1961 instructional film, *Land and Water: An Ecological Study of the Teotihuacan Valley*, recently updated by Kirk French (Kolb 2018). With David Webster he co-hosted "Out of the Past," an eight-part public television (PBS) series, comparing and contrasting Mesoamerican civilizations' and ancient Old World cultures, and created instructional videos and a companion college textbook, *Out of the Past: An Introduction to Archaeology* (Webster et al.1993).

Sanders trained nearly three dozen doctoral and Masters students and chaired numerous dissertation and thesis committees, https://anth.la.psu.edu/graduate/graduate-alumni. Among the Mesoamericanists were Joe Marino†, Dick Diehl, Charlie Kolb, Bob Santley†, Deb Nichols, Susan Evans, William G. Mather III, Jim Sheehy, Prudence and Don Rice, Rebecca Story, Dolph Widmer, Ken Brown, Steve Whittington, and Carson Murdy. His Eastern US archaeology doctoral students included Barry Kent, Ira Smith, Tim Senulis, Bill Womsley, Sam Casselberry, Sue Ann Curtis, Gary Webster, and Randy Turner. Non-Penn State students who became influential Mesoamerican archaeologists and Sanders' longtime colleagues were Jeff Parsons, Tom Charlton†, and Barbara Price†.

Joyce Marcus (2011:17–18) has cogently characterized his personal qualities:

> Sanders possessed enormous confidence and tenacity; great dedication to long-term goals; an ability to complete arduous tasks; tremendous loyalty to family, informants, students, collaborators, and colleagues; and an exceptional ability to debate with others, yet collaborate and learn from them He had the wisdom to see merit in divergent views and frameworks, and did not regard those who disagreed with him as rivals or enemies. Competition merely encouraged him to collect more field data. He also could draw on the ethnohistoric and ethnographic record, which he knew even better than his list of publications reveal.

Sankalia, Hasmukh Dhirajlal

Manoj Kumar Singh
Department of Anthropology, University of Delhi, Delhi, India

Basic Biographical Information

Hasmukh Dhirajlal Sankalia (Figs. 1 and 2) was born in Bombay on 10 December 1908 into an upper-middle-class Gujarati family for solicitors. He was born underweight and retained a frail constitution all through his life. Sankalia was dead in 28 January 1989. In 1959, Uma Vasudev, a journalist writing in the *Illustrated Weekly of India*, described Sankalia "as fragile as the potsherds he mends." Sankalia passed his matriculation examination in 1925, securing the highest marks in Sanskrit for which he won the Chimanlal Ranglal Prize of Shri Surti Dasha Porwad Hitechhu Sabha. His father and uncle wanted him to follow the family profession of law, but he joined St. Xavier's College to pursue the study of Sanskrit and History. Sankalia studied Sanskrit for his B.A. and History for his M.A. Sankalia passed his M.A. examination in 1933 with a first class and won the Pandit Bhagwanlal Indraji Prize of Bombay University. The thesis was published in 1934 as a book. Simultaneously with his M.A. degree, Sankalia also passed his LL.B. examination to satisfy the wishes of his father and uncle.

In 1934, Sankalia joined London University to do his Ph.D. in ancient Indian History. It was the influence of his teachers in England that eventually turned Sankalia's interest in Archaeology. He wrote his Ph.D. thesis on the Archaeology of Gujarat. This was the study of historical period

Sankalia, Hasmukh Dhirajlal, Fig. 1 Young Sankalia

Sankalia, Hasmukh Dhirajlal, Fig. 2 Old Sankalia

comprising art, architecture, epigraphy, and numismatics and was based on both field work and library sources. Sankalia got his Ph.D. degree in 1936. The thesis was published as a book in 1941 with financial assistance from London University (Sankalia 1941).

Sankalia was a life member of the Asiatic Society of Bombay; Bhandarkar Oriental Research Institute, Pune; Linguistic Society of India, Pune; and Indian Archaeological Society, New Delhi. He was the founder Chairman of the Indian Archaeological Society and continued in this position until he voluntarily resigned it in 1980 much against the wishes of the society's members. He was a member of the Permanent Council of the International Union of Prehistoric and Protohistoric Sciences from 1961 and Honorary Member of the Instituto Italiano di Prehistoria e Protohistoria, Italy, from 1962. He was a member of the following Advisory Boards of Archaeology: Government of India (1955–1975), Government of Maharashtra (1955–1974), Government of Gujarat (1964–1980), Government of Madhya Pradesh (1966–1974), and Government of Uttar Pradesh (1969–1978).

Sankalia was selected as a professor of Pro-Indian and Ancient Indian History in 1939 at the Deccan College Post-Graduate and Research Institute, Pune. This was Sankalia's first and last job.

Major Accomplishments

For his academic achievements Sankalia received numerous honors from professional organizations, the central and state governments, and the public at large in the form of fellowships, memberships of academic organizations, prizes, medals, nominations to prestigious bodies, invitations to deliver lectures and preside over conferences and seminars, felicitations by public bodies, etc. Sankalia received the Explorer's Medal from the Explorers Club, New York, in 1984. He was among the first batch of scholars to be awarded the Jawaharlal Nehru Memorial Fellowship in 1968. The President of India in 1974 conferred on him

the title of *Padma Bhushan* in recognition of his enormous contribution to archaeological studies.

The citizens of Maheshwar in Madhya Pradesh presented him a manapatra (citation) in 1954 in appreciation of his excavations at Maheshwar. The Municipality of Ahmednagar in Maharashtra presented him a manapatra and a shawl in 1973 "for bringing light in the history of Ahmednagar district form the dim past by excavation and exploration at and around Nevasa." Less than 2 weeks before his death, the Aitihasik Vastu Sangrahalaya of Ahmednagar presented him the Late Principal Naralkar Learning Prize at a function held at Deccan College.

Sankalia's first enterprise in prehistoric research was the expedition that he led to Gujarat at the instance of Rao Bahadur K.N. Dikshit, the then Director General of Archaeological Survey of India, in 1941–1942 to explore Stone Age remains, following the clues provided by the work of Robert Bruce Foote more than six decades earlier. In this expedition he included a geologist, a paleontologist, and a surveyor-draftsman. Sankalia located several new Paleolithic and Mesolithic sites in the Sabarmati valley in Mehsana district. One of the important Mesolithic sites was Langhnaj where Sankalia carried out several seasons of excavation jointly with his anthropologist colleague, Irawati Karve. Langhnaj was the first Mesolithic site to be excavated in India as also the first Stone Age site to yield physical remains of man. With this work Sankalia opened up a new and dynamic phase of research in prehistory. Sankalia published the results of his work both as a monograph entitled *Investigations into the Prehistoric Archaeology of Gujarat, Being the Official Report of the First Gujarat Prehistoric Expedition 1941–42* (1946) and in article in several journals (Sankalia 1942, 1955, 1956; Sankalia and Karve 1945, 1949).

The significance of Sankalia's work at Nevasa and particularly the discovery of a distinct Middle Paleolithic phase were recognized by the prestigious American journal *Science* when it invited him to contribute a paper on the Middle Paleolithic of India and Pakistan (Sankalia 1964).

The Government of India nominated him as a member of the archaeological delegation to the USSR in 1963–1964, cultural delegation to Yugoslavia in 1966, delegation to the International Congress of Orientalists at Ann Arbor, Michigan, USA, in 1967, and again at Paris in 1973.

Sankalia was elected Honorary Fellow or Member of the Ethnographic and Folk Culture Society, Lucknow (1974); Indo-Pacific Prehistoric Association, Canberra, Australia (1976); the Heras Institute of Indian History and Culture, Bombay (1977); and the British Academy, London (1986). He was nominated as a member of the Editorial Board of the prestigious British journal *World Archaeology* from its inception in 1969 and continued in this position until 1987. He was the Honorary Tagore Professor of Indian History and Culture at the M.S. University of Baroda from 1960 to 1965.

Sanogo, Kléna

Daouda Keita
Département d'Histoire et d'Archéologie, l'Université des Sciences Sociales et de Gestion de Bamako, Bamako, Mali

Basic Biographical Information

Kléna Sanogo (Figs. 1 and 2) is the Director of the Institut des Sciences Humaines, in Bamako, Mali. He is one of the country's leading figures, who has worked throughout his career for the protection and safeguarding of Mali's cultural heritage.

Sanogo, Kléna, Fig. 1 Kléna Sanogo

Born in 1948 in Doumanaba (Sikasso), Kléna Sanogo undertook his graduate studies at Voronezh, where he obtained a Masters in History from Voronezh State University (former USSR). He then worked at the Institut des Sciences Humaines as a Research Fellow from 1973 to 1974. This allowed him to participate in a number of archaeological excavations in Dogo (Bougouni) and to participate in archaeological research at Doupwill and Galia (Mopti) in Mali. Kléna Sanogo became the first Malian professional archaeologist. He was Director of the National Museum of Mali from 1974 to 1978. In 1980, he obtained the title of Doctor of Archaeology from Voronezh State University. In his role as Director of the Institut des Sciences Humaines since 1987, Kléna Sanogo has been instrumental in the implementation of numerous national programs of archaeological research.

Kléna Sanogo is an active member of several national, sub-regional and international professional associations and organisations; among these are the International Council of Museums (ICOM), the International Council on Monuments and Sites (ICOMOS), the West African Association of Archaeology (AOAA) of which he was President from 1996 to 1998, the PanAfrican Association of Prehistory and Related Studies (PANAF), and the Society of Africanist Archaeologists (SAFA).

Major Accomplishments

Kléna Sanogo has worked extensively towards the revitalization of archaeological research in Mali and the promotion of Malian archaeological heritage. He took an active part in the development of legislation and regulations on cultural heritage. In his role as Director of the National Museum of Mali in the 1970s, Kléna Sanogo was one of the key figures to set up a national Heritage Day in Mali. He also took an active part in the development of a new museum policy that led to the construction and inauguration of the National Museum of Mali in 1982. Kléna Sanogo also contributed to a large extent to the design and organization of exhibitions of national and

Sanogo, Kléna, Fig. 2 Kléna Sanogo at an excavation site

international scope, most notably the exhibitions on the Tellem and on the Vallées du Niger (1993). From 1985 to 1987, Kléna Sanogo led the archaeological components of the first the environmental impact studies in Mali in the reservoir area of the Manantali Dam and the gold mining area of Syama (Kadiolo).

The establishment in the 1980s of an inventory of archaeological sites in the region of the lakes and the inland delta of the Niger river gave a new impetus to archaeological research in Mali. Kléna Sanogo was one of the major players in the development and implementation of this project, which established the Institut des Sciences Humaines as the center of archaeological research at a national level. Moreover, this project allowed the training of a new generation of archaeologists. The results of this ambitious project were published in 1991 under the supervision of Michel Raimbault and Kléna Sanogo in Recherches archéologiques au Mali: prospections et inventaire, fouilles et études analytiques en Zone lacustre (Raimbault and Sanogo 1991).

Further of work conducted under his supervision includes archaeological research in Nioro du Sahel (1990–1995) and the pursuit of archaeological excavations at stone circle sites in Banamba, Nioro du Sahel, and Koulikoro (from 2003).

Since the early 1990s Mali has witnessed a revival in collaborations with overseas institutions and the implementation of new research projects, including the Togué project (an inventory of archaeological sites in the Inner Niger Delta) (1989–1992), the international archaeological excavations at Dia (1998–2002), the findings of which led to the publication "Recherches archéologiques à Dia dans le Delta intérieur du Niger" (Bedaux et al. 2005) and the program "Peuplement Humain et Paléoenvironnement en Afrique de l'Ouest" (Ounjougou) (1998–2010). This period is also marked by the organization of numerous African and international archaeological meetings in Mali. These include the meeting of the West African Association of Archaeology (AOAA) in Bamako in 1978 and at Djenne in 1999 and the 11th Congress of the PanAfrican Association of Prehistory and Related Studies (PANAF) in Bamako in 2001, which led to the publication of the proceedings under the direction of Klena Sanogo and Térába Togola (2004).

Sanoja, Mario

Lino Meneses Pacheco
Museo Arqueológico, ULA, Mérida, Venezuela

Basic Biographical Information

Mario Sanoja Obediente, for his career in teaching and research, is one of the most influential archaeologists in Venezuela. He was born in Caracas on September 12, 1934, and graduated in 1957 in the first class of the Central University of Venezuela-Caracas's School of Sociology and Anthropology.

Immediately following graduation, Mario Sanoja received a scholarship to study in France at the Ethnological Research Center of the Museum of Man and the Institute of Hautes Etudes de l'Amerique Latine under the mentorship of André Leroi Gourhan. In 1961 he met Betty Meggers and Clifford Evans who invited him to take a seminar on quantitative archaeology at the University of Barranquilla-Colombia where he met James Ford, Reichel-Dolmatoff, Carlos Angulo, Luis Lumbreras, Carlos Navarrete, and Olga Linares, among others, with whom he began a rewarding scientific relationship in the following years.

In 1963, Mario Sanoja established the Department of Sociology and Anthropology of University of Los Andes-Mérida. Together with fellow archaeologist and life partner Iraida Vargas Arenas, he carried out archaeological investigations from a regional perspective in Mérida's Range, Lake Maracaibo Basin, and the Quíbor Valley. This work marked the beginning of a period of change in Venezuelan archaeology because, in those days, research concentrated only on chronological sequences and lines of cultural diffusion established through the analysis of lithic and ceramic traditions.

In 1967, Mario Sanoja became a professor at Central University of Venezuela-Caracas, initiating a path that led him to investigate the ways of life and ancient geohistorical regions associated with the settlement of Venezuelan territories, producing, in co-authorship with Iraida Vargas, a

Sanoja, Mario, Fig. 1 Mario Sanoja Obediente

series of archaeological papers, scientific articles, and presentations in national and international congresses and seminars. These make it clear the historical processes developed by the native peoples, their relations with other societies, and native cultures to the North of South America and insular Caribbean (Fig. 1).

Major Accomplishments

The 1970s and 1980s was a period of meetings and exchanges that materialized Latin American Social Archaeology; Sanoja Obediente would be among its founders. Following the symposium on "Native American Formations" held in 1970 at the Congress of Americanists in Lima, Mario Sanoja and Iraida Vargas published in 1974 *Venezuelan Ancient Formations and Modes of Production. Notes for the study of integration processes of Venezuelan society (12,000 BC–1900ª. AD.).* This book sought, from the archaeological evidence of these years, to interpret the history of Venezuela from a Marxist perspective. Moreover, it encouraged no epistemological rupture between the study of ancient and modern societies and constitutes a transverse axis in Mario Sanoja's work that was also displayed in his book *The Yucca and Maize Men. An Essay on the Origin and Development of Agrarian Systems in the New World* (Sanoja 1982).

In his publications, Mario Sanoja postulated the concepts of space-domestic-group, space-territorial-group, and geohistorical region for the inference of archaeological contexts (Sanoja 1997). These were useful conceptualizations to characterize archaeological contexts in connection with social relations and production and reproduction conditions of the material and immaterial basis of any given social economic formation. He contended that the application of the concept of geohistorical region in archaeological inference would allow us understand the qualities of the uses of a determined geographic region by territorial groups, which were themselves constituted by domestic groups (Sanoja 1997).

Mario Sanoja not only elaborated important theoretical proposals but, together with Iraida Vargas, applied the ethical-evaluative postulates of social archaeology, turning it into a socially useful science in the sense of directing archaeological practice toward a search for solutions to our communities' problems. From this perspective, they published several proposals, among them, the book *History, Identity and Power* (Vargas and Sanoja 1993), in which they discussed the origin of the Venezuelan nation, the cultural heritage, and the historical-cultural patrimony; the problems of teaching history in Venezuela; and the role of museums as educational tools, all articulated with the question of identity as a strategic element for the consolidation and defense of national sovereignty.

In 1990, Mario Sanoja organized the Second World Archaeological Congress (WAC-2) in the city of Barquisimeto-Venezuela. He was appointed as Academic Vice-President for this Congress. From 1995, he published a number of books that made groundbreaking contributions to archaeology in Venezuela: *Canoe People. Political Economy of the former Appropriation Society of north-eastern Venezuela* (Sanoja and Vargas 1995), *Water and power: Caracas and the formation of the Caracas colonial state: 1567–1700* (Sanoja and Vargas 2002), *Guayana's Ages. Archaeology of a Chimera. Santo Tomé and the Catalan Capuchin Missions 1595–1817* (Sanoja and Vargas 2005), and *The Dawn of Venezuelan Society* (Sanoja 2013). In the first book, Sanoja and Vargas discuss, for the first time, the role of women in the Appropriating Social Formation period and the ways of life of collectors who settled in about 8000 BC in the Caribbean littoral zone and Venezuela Atlantic coast. In the second

and third books, they combine archaeological field data and the *Indias* texts, to explore the Venezuelan colonial way of life as a particular form of capitalist social formation that was implanted in Venezuelan territories as part of the European conquest of these territories in the fifteenth century. In the last book, within the geohistorical context, the native colonization of Venezuelan territory in the Caribbean and South American context is discussed in order to highlight the temporal and territorial continuity of that process (Sanoja 2013).

His work marked the way of doing archaeology in this country and today influences by its theoretical postulates in the research that is carried in present.

Santa María, Geography and Culture of

Javier Nastri
CONICET, Depto. de Cs. Nat. y Antropológicas + Fundación Azara, Universidad Maimónides/ Universidad de Buenos Aires, Buenos Aires, CABA, Argentina

Santa María is the name of an Argentine city located in the valley that holds the same name. It is also used to refer an ancient indigenous pottery style as well as the archaeological culture defined by the researcher Alberto González (1950). Santa María funerary urns for the burial of children constitute the best known objects from pre-Columbian times in northwest Argentina displayed widely in many museums around the world.

The city of Santa María owes its name to the fact that it has been developed near the site of the ephemeral seat of the Jesuit mission "Santa María de los Ángeles de Yocavil" founded in 1618. "Yocavil" was the name of an indigenous tribe from the South of the valley. This extends from Punta de Balasto, in the south, to Cafayate, in the north, place of confluence of the rivers Santa María and Calchaquí. Both Santa María and Calchaquí valleys, along with the Quebrada de las Conchas-Valle de Lerma, form the group called "Valles Calchaquíes" extending throughout the provinces of Catamarca, Tucuman, and Salta. However, the sphere of interaction in which Late Intermediate societies produced and consumed Santa María ceramics was much wider, including at least the adjacent valleys of Cajón, Tafí, Quebrada del Toro, and the piedmont of Tucumán (Sali river basin).

Santa María is a broad valley running in south-north direction (Figs. 1 and 2), about 12 km wide by more than 100 long, with an average altitude of 1900 m. It is delimited, by the mountain range Sierra del Aconquija and Cumbres Calchaquíes in the east and by Sierra del Cajón (also called Quilmes) in the west. The climate is arid with annual average temperatures reaching 16 °C and the

Santa María, Geography and Culture of, Fig. 1 Overview of Santa María valley from sector VI El Carmen 1 site (Tucumán province). In the background, the mountain ranges of Sierra del Aconquija (right) and Cumbres Calchaquíes (left, corresponding to the north)

rainfall minor than 200 mm. Rains are concentrated between October and April.

Vegetation is xerophilous; carob and *chañar* stand out as the unique native trees highly regarded due to the benefits their seeds and pods provided for food preparation. Among the native animals, the main species are camelids as guanaco (*Lama guanicoe*), vicuña (*Vicugna vicugna*), and llama (*Lama glama*); cervids as *huemul* (*Hippocamelus antisensis*); flightless birds such as partridge and brokerages as the rhea (*Pterocnemia pennata*); rodents like *chinchillas* and *viscachas* (*Lagidium viscacia*); *quirquinchos* (*Chaetophractus vellerosus*); hares; foxes; and pumas.

Vast majority of Santa María river collectors are dry during nearly all year. The most important are those that run along the western slope of the Sierra del Aconquija, yielding some fertile oasis on the eastern side of the Santa María river as Ampajango, Jujuil, and Entre Rios in a desert general context that contrasts with the western band river, where the distribution of the little available water is more uniform, leading the growth forests of carob, a resource heavily exploited by ancient farmer populations.

Late Indigenous Populations

Countless names for different populations who took part in the political events occurred in the Calchaquí valleys during the Spanish conquest were included in the historical chronicles of sixteenth and seventeenth centuries. Some of them are *tafíes*, *acalianes*, *pacciocas*, *ingamanas*, *pulares*, *pichaos*, and *quilmes*. The meaning and extent of each one of these names is a matter of debate until the present due to Spaniards lacked of precise conceptual tools to account for a different cultural reality. Modern historical studies evaluated the scope of the various denominations, understanding some of them -calchquíes, diaguitas- as terms refferring also to more inclusive groups of people culturally related. This way, they began to be used to name hole populations

Santa María, Geography and Culture of, Fig. 2 Map showing the location of the sites mentioned in the text

along big areas. According to the new chronological criteria introduced in the regional archaeology by the mid-twentieth century, González suggested the replacement of the general term "diaguita" by the designation of cultures Santa María and Belén (González y Pérez 1972). Both correspond to the geographical distribution of the characteristic ceramic styles: Santa María at the north includes

Calchaquí valley, Quebrada del Toro, Quebrada de las Conchas, Valle de Lerma, Tafi valley, Santa María valley, Cajón valley, and Tucuman hillfoot (Fig. 2) and Belén, in the South, comprehending Hualfín, Abaucán, and Andalgalá valleys.

The archaeological remains of Belén and Santa María cultures are indicative of Late Intermediate Period (1000–1450 AD) -also known as Regional Development Period (Núñez Regueiro 1974) - in the Argentine northwest. In Santa María valley, the settlements were placed on the slopes and peaks of the hills (Fig. 3) naturally protected against potential sieges, while defense walls and other military structures such as parapets (Fig. 4) and watchtowers were also added. Constructions ranging in numbers that could exceed 200 or 300 compounds were built along the slopes, the foothills, and adjacent areas, while the agricultural infrastructure was located at the bottom of the valley. In the high altitudes of Sierra del Cajón, small installations for handling herds of *llamas* were constructed, and there is at least one known case, Pichanal 4 (Cantarelli et al. 2014) of a pastoralist aggregation site possibly held to perform ceremonies linked to the cattle reproduction cycle. Finally we should also mention defensive positions consisting of a few enclosures and stone walls of large dimensions located at strategic places.

Santa María large settlements were built mainly in stone and have been defined as *clusters* (Madrazo and Otonello 1966) or *populated centers* (Nastri et al. 2012). Many authors point out that these large dimensions are indicators of an increasing population (Nunez Regueiro 1974; Tarragó 1995; etc.). The truth is, as discussed below, that very little is known about the previous developments in the area. When it comes to the Late Intermediate Period, a number of variations on Santa María settlement and pottery are appreciated throughout the vast territory.

Regional Variation

Archaeological sites at the west of Sierras de Aconquija-Cumbres Calchaquíes are better known because of the use of stone in architecture

Santa María, Geography and Culture of, Fig. 3 View of enclosures on the slopes of Cerro Pintado de las Mojarras site (Catamarca province)

Santa María, Geography and Culture of, Fig. 4 Circular enclosure at Las Cañas site (Tucumán province)

with walls of about a meter from the surface providing the possibility of making an assembly drawing for at least some of the residential units that count in a number of cases, with more than 100 structures. In the eastern sector, instead, research has been scarce owing to the abundant vegetation which constitutes an obstacle for visibility. The few sites known in this area belong to cemeteries or lowlands settlements with no fortifications identified.

Santa María populated centers in the semiarid valleys of the west may extend about 60 ha and harbor about 300 structures in rock taking into account buildings, retaining walls, defensive walls, and roads. Structures are displayed on the top of an immediately adjacent mountain to the flat lands in which many other buildings can be seen. In those cases where the topographic conditions of the area allowed, settings were also built over the mountain slope. This implied the Calchaquí villages being separated from the agriculture and collecting areas. Hunting was also practiced in high altitudes where camelid herding also took place, evidenced by posts of temporary use, also made of stone.

Differences on settlement arrangement between the eastern and western bands of Santa María river occurred owing to variations on the provisioning source of raw materials employed for building construction as well as the terrain differences contributed to shape the layout of settlements. These differential patternings led to archaeologists as Tarragó to establish two types of populated centers: *Rincón Chico pattern* corresponds to the western side of the river. In this, buildings extend from the top of the mountain, where metamorphic schists abound, along the slopes and the alluvial fans to reach river floodplain. Stones were disposed vertically as the founding of structures and then stacked horizontally to conform double-lined walls which could be filled with sediments. The thickness of the walls varies between 70 cm and 1.20 m. On the other hand, *Loma Rica pattern* takes place on the eastern side of the river. There, sedimentary conditions resulted in mountains with flat summits, selected by ancient inhabitants for installation. Here slopes lack of the suitable conditions necessary for building, so structures are found at the top of the mountain and at the bottom. Masonry is

constituted by stones with sphere shape. The sites corresponding to Loma Rica pattern are located near to tributaries of the main rivers but not on the valley floor (Tarragó 1995).

Stone buildings were displayed along the landscape isolated or associated with others in variable numbers. The rectangular compounds over the rugged slopes shared the shorter walls, showing a lineal disposal. Assemblies with rectangular shared courtyards are frequent in flat lands on the foothills in Rincon Chico pattern sites while occurring on the hilltops in Loma Rica pattern sites. In Rincon Chico, these courtyards are rectangular with broad dimensions (about 10 × 15 m). Between one and five circular or quadrangular rooms were associated with a courtyard through the presence of openings. Whereas rooms could have been covered completely by roofs, courtyards were surrounded by a gallery held on posts.

Along Cajón valley, the spatial location corresponding to both models inverts: on the eastern side of Cajón river, sites as Famabalasto (Cigliano 1958) correspond to Rincón Chico pattern, whereas on the western side, sites as Loma L'antigo (Bugliani 2012) match with Loma Rica pattern. The nature of the mountainous formations as well as the raw material available for the construction of buildings in these areas has determined the spatial inversion of settlement configurations in comparison with Santa María Valley.

In Calchaquí valley, there is a clear contrast between the localization of settlements during the first phase of Late Intermediate Period, from the subsequent phase: initially, villages were settled at the interior of the tributary streams of the main river, and later population concentrated in bigger settlements along the Calchaquí river (De Marrais 2001: 312; Baldini 2010: 54). These settlements were installed on the low terraces on the limits of crop areas (e.g., Valdez) whereas other compounds (e.g., Borgatta) were established over the alluvial fans next to the rivers and reaching the foothills of the neighboring mountains (De Marrais 2001: 318). The settlements could host more than 200 residential units, with open spaces and a big number of mounds corresponding to mortuary functions and refusal concentrations areas (De Marrais 2001; Baldini 2010).

Sites as Tero, El Churcal, and Molinos I in the Calchaquí valley display a particular constructing technique which consists on digging the surface that will be used as the building's floor and covering with stones the sides of the big pit. The attachment between the compounds generates the effect of double-lined walls (Baldini 2010: 58).

In Tapia-Trancas basin, on the eastern side of Calchaquí peaks and Aconquija Mountain range, archaeological visibility is reduced, and, unlike the semiarid valleys of the west, few researches were made. Nonetheless nearly 20 sites corresponding to this period have been recorded (most of them now sunken under the waters of El Cadillal dam). Most of the sites display ceramic fragments dispersed over the ground, burials, rectangular depressions on the ground with the presence of rocks over the surface, and remnants of cultivated fields (Esparrica 2003). In Zárate, a cemetery was excavated composed by 13 cists with walls made of stone in false dome constituting collective burials, two adults primary burials, and more than 50 Santa María urns which belonged to the phases tricolor, bicolor, and ordinary with maize traces stamped, used for children burial (Esparrica 2003). The housing compounds are located over the hill on the other side to the Acequiones river.

Mortero Hachado is the biggest Santa María site known in Tucumán foothills extending along 40 ha. Burials of adults, primary and secondary, along with the presence of bowls and urns have been recorded.

Most of the abundant cemeteries from the Late Intermediate were excavated massively by researchers, looters, and smugglers during the first decades of the development of Argentine archaeology. In recent times, the cemetery of Rincón Chico 21 has been excavated, and 15 subterranean cists with slab roofs and the same amount of urns for the burial of children, two direct burials, and a charnel house were registered.

Santa María pottery is widely spread along the landscape: from the proximity of the actual city of Salta on the north, to the valley of Belén in the

south, Antofagasta de la Sierra on the west, and Tucumán foothill on the east (Fig. 2). Caviglia defined four areas that correspond to sub-traditions: *Yocavil*, corresponding to the Santa María valley and its adjacent area, Cajón valley on the west and Tafí on the east; *Calchaquí*, corresponding to the homonymous valley; *Valle Arriba*, where the two last mentioned areas merge; and Santa Barbara or *Pampa Grande*, the eastern sector already mentioned.

Interactions among the populations from different valleys have been a matter of interest in recent times. Researchers as Tarragó argue that Tafí valley provided apt lands for cultivation of microtermic species as potatoes and camelid herding exploited directly by communities in the Yocavil valley. Manasse rejects this hypothesis on the grounds that it consists on an aprioristic peripheral role to the Tafí valley (Manasse 2014). The settlements of Late Intermediate in Tafí were isolated rectangular structures in groups till five located along the lowlands. The walls were made of mud with the occasional appearance of stones. Frequently habitations are associated to mounds of variables sizes. These compounds may have been articulated to other structures, generally quadrangular that were employed as enclosures for camelid herding. This kind of structures has been also documented in the mountain range neighboring the valley.

Late Stone Architecture in Santa María Valley

Residential enclosures constitute the most frequent type of structures in late settlements of Calchaquí valleys. They spread out as single or composed units, sharing walls with other enclosures alike or large courtyards denominated "canchones." These compounds lie along the alluvial fans and foothills, while the simple isolated units appear associated in pairs or lineally arranged perpendicular to the gradient of hilltops and slopes.

Courtyards vary from 5 × 10 to 15 × 40 m and may not be completely enclosed. They hold an entrance or two that communicate with the exterior. Several activities such as food processing and manufacturing of pottery and metals took place inside these structures (Tarragó 1995: 227). Connected to this rectangular enclosure are the rest of the rooms. The attached small circular buildings (Fig. 4) with narrow (50 cm) and low (1 m) entrances held storage functions. Other rooms operated as cooking and housing places. In the high altitude herding posts, the assembly of structures (generally corresponding to the circular type) were minimal, probably having the same room the twofold function of housing and cooking.

All openings were narrow (no more of 60 cm length) and surrounded by a wood frame that made the orifice even smaller. The walls were erected using slabs in the side posts displayed vertically as jambs. The lintels were made of big straight slabs. Ramps were used in several cases as a way of access to the compounds. The top of the walls operated as platforms for circulation along the slopes covered by constructions, and content walls were also used to flatten the ground.

Small irregular rooms associated with the compounds could have been used as little storage settings; some of them lacked an entrance.

Housing grounds were formed with the simple use of the surface, although there are cases of floors on live rock over the mountain slopes.

Roofs haven't been preserved in any of the sites known. They were made of branches filled with mud and wicker or could lean over cross-pieces of carob tree. Wooden posts were registered in Quilmes during the late nineteenth century. It is possible that the small circular rooms had conic roofs, suggested by the founding of central settings for hole posts in buildings in Rincon Chico 18 (Tarragó 1995: 227) and El Carmen 1 sites. Rectangular rooms could have counted with shed roofs.

Over the mountain ridges, big slabs of 2 m tall by 1 of width are displayed along the roads of access with a manifest defensive propose (Tarragó 1987: 188). In areas where the preservation is poor, and given the large dimension they can hold, these parapets can mislead the interpretation toward the founding typical slabs of these period walls. The parapets are well articulated with the

walls obstructing the ascent of potential enemies. These walls can be relatively short, as well as those which constitute the limits on the peak sectors. They can also be very high (with 6 m of height) with steps disposed at different levels of the slope (in some cases twisting and articulated with the watchtowers, as in Cerro Mendocino); or they can also be medium height, as in the case of the large walls that avoided the entrance to the populated centers located on the debris cones formed by piled rocks.

Watchtowers were small and circular buildings articulated with the defensive walls along the mountain slopes. They had an entrance opening, and some of them counted with steps formed by protruding slabs. In Cerro Mendocino – the greatest fortress of Santa María valley – pebbles that could have been taken there as projectiles used in the defense of the settlement were found inside these structures (Carrara et al. 1960: 31).

As far as the productive infrastructure is concerned, enclosed yards designated to camelid herding stand out in their different varieties: circular, rectangular, or irregular. They stand out on the high mountain posts, contrasting the small circular structures that worked as shepherd shelters. In the case of the populated centers, these farmyards can be easily confused with the characteristic large courtyards described above. Studies on phosphorous of the sediments inside one medium size enclosure in Morro del Fraile allowed determining its function as a farmyard for camelids in past times (Nastri et al. 2012).

Agriculture was practiced by means of cropping platforms made of lines of stone over the soft gradient slopes, irrigated by channels that extracted and distributed water from the rivers. Attached to these terraces, storage enclosures were located, while the accumulations of rocks as a product of the cleaning of terrain rest in the adjacent parcel. Quilmes dam is the best documented structure in the area for water storage. A ridge that formed semicircular arch was used and continued with a low stone wall to enclose the gap held with the mountain. A narrow small door constituted the opening by which the water flowed through a big orifice made on a rock block. Las Pailas is one of the largest sites documented for agricultural production, embodied by an intricate and well-preserved network of surface and underground irrigation channels (Paez et al. 2012). As well as Quilmes dam system, it is up to be determined whether this structures correspond to the Late Intermediate or to the subsequent Incaic period.

In the settlements of the west band of Santa María river, people harbored a number of orifices for grinding activities, denominated mortars, over plenty of big rock blocks (till 3 m high) that lay dispersed on the floodplain. They were also carved in live rock at the foothills probably for public access.

One of the megalithic rocks which contain mortars and petroglyphs is associated with ritual activities that took place in sector I of the site of Pichao (Fig. 5). This rock is located over the perimeter of a circular mound delimited by short walls of stones with a smaller elevated circle inside, with the same building technique applied. It constitutes a two-level platform in which interior a burial of a 5 year old boy in a Santa María urn from the variety "Valle Arriba" was found, together with beads from a ceramic necklace, malachite, azurite, and bones. There were also isolated animal bones and carbonized seeds and fruits (Tartusi and Nuñez Regueiro 2001: 91–93). The shape of this structure coincides with the descriptions of the indigenous temples given by the chronicler Lozano in middle eighteenth century (Tartusi and Nuñez Regueiro 2001: 97).

There are differences in the construction material used in this structure: white quartz stones were used in the north section, while gray colored ones were used in the rest of the areas. The resource of different color rocks interspersed was employed in diverse settlements of the western band of Santa María valley. The most remarkable example is that of Rincon Chico, where the bonding between the rock disposition and astronomic phenomena has been demonstrated. A plaza at the bottom of the *Puma ravine* embraces a sequence in which rocks of white quartz appear arranged lineally on the upper eastern wall contrasting with the leaden gray slabs of the remnant structure. Half way up the hill, there is a semicircular room built on dark slabs which exhibits two blocks of quartz inserted

Santa María, Geography and Culture of, Fig. 5 Ceremonial mound at Pichao site (Tucumán province)

on each side of the external wall. Finally on the upper sector of the hill, a third structure forming a terrace displays gray slabs, blocks of white quartz, and granitic pink blocks. Right over of the straight line projected from these aligned structures, the sun rises during the summer solstice (Reynoso 2003).

Ultimately, it is important to note the mortuary structures constituted by underground chambers. They can present tiled floors and roofs on false domes made of slabs that stand out off the external sides of the walls. The plan shape of these cists varies from circular, ovoid, or rectangular. In the instances where the cists lack from domed roofs, there are plain slabs as covers instead (Johansson 1996).

Debates Regarding Social Organization During the Late Intermediate Period

Social inequality was a subject of concern since the development of the first investigations about Calchaquí settlements. Lafone Quevedo felt overwhelmed of by what he thought it look like the kingdom of the "Republican equality" when wandering among the remnant buildings of the Quilmes site. Adan Quiroga suggested the existence of specific structures that functioned as a residence for the authorities of La Ventanita site in Fuerte Quemado. Once historical sources from the time of the conquest began to be studied profoundly on first decades of twentieth century, authors began to make projections backward of the scenery provided by the documents in which political fragmentation, internal wars, and an overall background of simple or rudimentary life conditions stand out.

The first approach to social organization based exclusively on archaeological evidence was introduced by Madrazzo and Otonello in 1966, on the basis of the comparison between a vast number of sites registered. The authors came to the conclusion that no solid grounds based on archaeological register could account of specialization or social stratification in the past. At very least there could have been a "rudiment of function specialization" visible by the way of chief housing structures or specific settlements for the performance of religious ceremonies (Madrazo and Otonello 1966: 11).

During 1970s, some researchers began to consider Late Intermediate societies of northwestern Argentina as chiefdoms with a "sociopolitical organization" complexer than that developed by the native populations during the precedent periods in the region (Nuñez Regueiro 1974: 182–183). The idea of the existence of a system or a rank society was discarded; however, the proposal of specialization on the making of goods as textiles and metals gained acceptance. Cigliano and Raffino argued that in Tastil, social differences existed in the form of family lineages (Cigliano and Raffino 1977: 19).

From the second half of 1980, the first results shown by the researches of Yocavil Archaeological Project in Rincon Chico thrown light on the existence of architectural differences at the interior of sector 1, which were interpreted as the material correlate of social differentiation among the residents of the different neighborhoods (Tarragó 1987). The hypothesis that differences on altitudinal location at the interior of the settlements locations had meaning in terms of social status then gained sustainability.

An interest fact to remark is a legal litigation in sixteenth century in which blood nobility is manifest among Calchaquí people, as well as differential economic rights for the chief and his family (Palermo and Boxaidos 1991).

Berberián and Raffino employed the category of chiefdom consistent with the theoretical propositions of Elman Service. According to these approach, there is a power structure in which the chief is on the top, followed by the other social ranks. Years later, analysis carried out on archeometallurgical material recovered from Rincón Chico 15 lead Tarragó and González to put forward the existence of productive specialization sponsored by the dominant elites so as to replicate and increment their power. To achieve this goal, the elites would have manipulated the production, distribution, and use of goods to reproduce the hegemonic ideology (Tarragó and González 1996: 88).

Contrasting to the ideas presented, Nielsen strives for the abandon of the term chiefdom applied to these societies owing to three main difficulties this concept generates: (1) the incapability to account the great variability among the sedentary stateless societies that exhibit inequality and heterogeneity only in incipient grades; (2) its qualifying nature, rather than explanatory, based on stereotypes of ethnographic foundations; and (3) the tendency to employ ethnographic cases to explain problematic facts when archaeology fails to provide an accurate answer (Nielsen 1995: 23).

Aligned with the objective of recovering the variability and originality of the indigenous organizational forms as well as stepping aside the classification of forms of life into an evolutionary scale, the theoretical framework elaborated by Ben Nelson for the study of complexity in North America is taken into account for the Calchaquí case. Nelson argues that instead of determining *how much* complex these societies were, the focus should be set on *how* this complexity was developed (Nastri 1997–1998: 266). In this direction, knowledge about settlement for the western band of Santa María valley was used for the grouping of sites with complementary functionality on bands running transversally to the main river. These groupings could include two population centers, one of bigger dimensions than the other (Nastri 1997–1998; Coll Moritan and Nastri 2015). The question about the kind of exchange networks (defined by Renfrew in the decade of 1970) that took place among the centers belonging to the same settlement pattern (reciprocity and redistribution) and among the social groups represented by distinct settlement patterns along the valley (chain interaction, direct exchange or through emissaries) is to be answered. Countless changes occurred concerning to economic and politic integration during the long time span corresponding to Late Intermediate, Imperial, and Hispanic-indigenous periods (Nastri 1997–1998).

Acuto recovered the interest in the *how much* of the complexity, but divorcing from the perspectives which considered Calchaquí societies positioned at an elevate place into the evolutionary scale, and pointing out the absence of the necessary archaeological evidence to validate these assumptions. He argued that the general circumstances during this period were characterized by a "communal integration," "a symbolic and

material homogeneity," and a "social control and vigilance upon the development of inequality" (Acuto 2007: 75). Nonetheless the author does not provide definitions about these concepts nor supply the material correlate examples to be contrasted by the archaeological evidence. Without any detailed analysis of the materials and their temporal and spatial distribution, absence of evidence is equated by the author to evidence of absence. Finally, Acuto pointed out that Santa María as well as middle and south Catamarca constituted exceptions to the previous propositions of "communal integration"; thus manifesting the alternative position of "fragmentation."

Coll Moritan and Nastri (2015) adopt a relativistic position in which they consider complexity as constituent to all societies. Each of them is original and deserves to be studied in detail through the focus on positive features. This means an interest on actual material findings instead of considering apparent absences of elements included in general classificatory lists. The study of settlement patterns and hierarchies and residential segregation are two ways to approach past social and economic organization. The authors documented the association of populated centers in uneven pairs separated by minor distances than 5 km (Fig. 2). They also recognized the complementary economic functions of the site of Morro del Fraile, located inland mountain range, and the settlements next to the agricultural lands on the bottom of the main valley or in little transversal valleys. This way they pointed out how ancient populations could access the vital subsistence resources. Secondly, the researchers examined the differential distribution of types of walls among diverse sectors of the settlements (Coll Moritan and Nastri 2015: 75), highlighting the existence of sectors where some specific constructing techniques were employed in contrast with the rest of the habitations of the settlement. Apart from the selection of color (preserved in Rincón Chico and also registered in other neighboring populated centers), walls of aligned slabs are disposed presenting a soft uniform surface. This effect can be reach by a previous preparation of the slabs. Experimental studies as well as systematic measurements are required to evaluate the differential distribution of this stylistic architectonic device that may cast light on residential segregation, as what was the case of Rincón Chico.

To summarize, complexity among Late Intermediate societies as well as regional differences constitutes subjects of current investigation. Recent studies on the representation of human figure add another line of evidence to the discussion about Calchaquí social organization and their archaeological indicators.

Santa María Iconography

The existing knowledge of the material depictions displayed by the Late Intermediate societies comes from the study of museum collections constituted as a result of the massive excavation of burials during the last decades of nineteenth and the beginning of twentieth century. Santa María ceramic urns (Fig. 6) and discs, axes (Fig. 7), and bronze bells were the most outstanding items of this early collections. However, the most detailed analysis of mortuary contexts were carried out as a consequence of Muniz Barreto expeditions during 1920s, where a broad spectrum of the material culture from Late Intermediate Period in Santa María valley was recovered. Contextual analysis began in 1950 from the studies of González (1950) and Cigliano (1958) and continues to the present (e.g. Matera 2008). The Santa María urns for the burial of children are complemented by other numerous archaeological findings: the bowls and the big funerary urns for children up to 12 years old, a rich variety of ceramic types (cooking pots and beakers of varying sizes) with or without decoration in different colors or with surfaces crossed by irregular incised lines; ceramic human figurines; mortars, pestles, and stone axes; monoliths representing human figures made of wood or stone; and bronze axes, knives, mittens, bells, shields, anklets, chisels, and tweezers. Where there are good preservation conditions, little basketry bowls and knitted textiles were also found.

The burial urns to which the name of Santa María was first applied are constituted by a body

Santa María, Geography and Culture of, Fig. 6 Santa María funerary Urn (inventory number 87155, Welt Museum Wien, Schreiter collection)

and a neck, with lateral handles on the body segment (Fig. 6). The surfaces are smoothed and present a white covering on which motifs, mainly in black and sometimes also in red, were displayed. As it has been noticed by many researches, there was an intentional rejection to empty spaces inside pictorial fields.

Images displayed on the urns surface are arranged by a twofold disposition demarcated with strips on the sides that conform the limit between the front and the back of the piece. The urn itself constitutes an anthropomorphic metaphor visible on the inflection point between the neck and the body. A contrast as the existing between the human head and thorax is thus accomplished and intensified by the depictions that highlight other human features.

The anthropomorphic being indicated by modeling and painting is known as the "figure of the long eyebrows" (Nastri 2014: 95). Its face is arranged along the neck of the urn and the thorax displayed along the body. There are no clear indications of lower limbs. This basic scheme has an occurrence frequency superior to 90%. Only in 1% of the cases other motifs are displayed on the neck of the urn (as animals by front or profile), and in 5% of the cases, geometrical motifs are

Santa María, Geography and Culture of, Fig. 7 Bronze axe (inventory number 86552, Welt Museum Wien, Odt collection

depicted, similar to those contained in textiles. This last mentioned feature can be indicative of a way of representing the "long eyebrow figure" as a mummy covered its head with clothes (Velandia Jagua 2005: 117–118).

Cephalic masks and ornaments are depicted over the urns on the early phases, and faces with aggressive expressions are characteristic of phases III and IV (Fig. 6). These traits allowed the researchers to associate the "long eyebrow figure" with important political functions, such as those exercised by shamans and warriors (Nastri 2014: 96). The other motifs displayed - snake, rhea, humans, in this order of frequency - are subordinated to the central figure. They are depicted by pairs in the neck or the body of the urn with the exception of toads in phase 0 vessels, where they may appear as the only one figurative motif in the body of the urn. The snakes depicted over the neck of the urns sometimes may represent a cephalic ornament (Nastri 2014: 96), and rheas are displayed as if they were facial paintings of the figure of the long eyebrow. In line with this, a great number of abstract geometric designs in the neck can be interpreted as representation of tattoos.

Imperfect symmetry is a procedure utilized on design patterning. It is constituted by the layout of the motifs in two opposing planes that structure the overall arrangement of the design. The former artisans included deliberately *slight differences* – on shape, type, or quantity of motives – in mirror symmetry between the front and the back as well as in the relationship between the right and left side of each cheek, or body sides that pass unnoticed at first sight. Complementing this mode of representation, the natural asymmetry of human body over a horizontal axis is altered through creation of "artificial" symmetries. As the bottom of the urn is constituted by a bowl, habitually, urns were covered by bowls at the top. A black curved triangle under the arms of the figure of long eyebrows is depicted (Fig. 6) as a procedure that generates a relation of mirror symmetry with the motif disposed over the eyebrows of the personage.

Santa María art pursuits a fusion of identity and difference. Through the use of symmetry, it becomes clear there was an intended purpose to show different objects as if they were similar, and, at the same time, to show things that are similar as if they were different. This elaborated symbolic system is likely to be also constituent of the ceramic group denominated San José. This ceramic group took part in funerary contexts and was present in everyday life during the first moments of Late Intermediate Period (Marchegiani 2008). The study of this style in detail has not been undertaken until recent times (Palamarczuk et al. 2015).

Rock art remained as a regular practice during the Late Intermediate in Calchaquí valleys, represented by paintings or stone engravings with a reduction in the variety of motifs depicted in comparison with earlier times. Caravans of *llamas* stand out (Fig. 8) as well as human depictions wearing clothing or shields. Cerro Cuevas Pintadas in Guachipas (Salta province) constitutes an exceptional case with more than 30 caves and rock shelters with polychrome depictions (Podestá et al. 2005). There, as in Calchaquí valley, the Puna, and north of Chile sites, researchers have documented a symbiosis among the representations of men with shields and axes, as if their referents were exchangeable. The concept of "axe-men" came up owing to these depictions (Montt and Pimentel in Podestá et al. 2013: 86) that exceed the Santa María context to become a mark of the period over a broad area. Santa María ceramic style acquires a remarkable significance on the subject due to the fact that urns collections contain great numbers of human figures for comparison. Several connections can be made among the depictions over ceramics, rock art, and textiles (as differential representations or transpositions of motives). These representations are connected to power relationships given during Late Intermediate and related with groups consolidation processes over territory. Transformations and resignifications of these representations were employed by the Incas to establish their domain over the region (López Campeny and Martel 2014: 47). The two different varieties in the axe-men depictions would correspond to different social functions. "Shielded men" figures would have symbolized political or ritual authorities;

Santa María, Geography and Culture of, Fig. 8 Rock carvings at El Carrizal 5 site (Tucumán province)

while the "T"-shaped human figures would have been linked to the military sphere. Finally, the overlapping motifs corresponding to different temporalities exhibiting an exaggerated size would constitute expressions of resignificance practices destined to the creation and reproduction of the social memory (López Campeny and Martel 2014: 48).

Origins of Late Intermediate Way of Life

The lack of evidences corresponding to the previous centuries before the Late Intermediate led researchers such as Tartusi and Núñez Regueiro to suggest a geographical displacement of the development centers from a period to another. Thus, the formative centers (250 BC–600 BC) of Campo del Pucará would continue throughout the Middle Period -also known as Regional Integration Period - (600–900 AD) along Ambato valley, and finally Santa María valley would acquire prominence during Late Intermediate (Tartusi and Nuñez Regueiro 1987). Fieldworks carried out along the last few decades have begun to provide the necessary elements to complete the local sequences backward and onward on time. Middle to Late Intermediate Period transitional settlements have been identified on different sectors of the valley (Scattolin 2010), and also Middle Period sites without continuity in Late Intermediate Period have been discovered. Bañado Viejo, located in Tucumán province, is a fine example of the latter, where a Middle period component was isolated and named *Colalao phase* by Scattolin (2010). Little is known about architecture and settlement patterning during this time owing to the limited extension of excavated surfaces. And in settlements with components from Middle and Late Intermediate Periods –as Morro de las Espinillas and Morro del Fraile – it results very hard to distinguish accurately the period in which architecture structures were built. At least, it can be pointed out that middle populations located their villages over high topographies, anticipating the Late Intermediate settlement way of life. In Morro del Fraile, the pottery recovered correspond to both Middle and Late Intermediate Periods. In the rock shelter as well as in enclosures located over the slopes,

occupations for both periods were dated (Nastri et al. 2012). It is possible that the transition to Late Intermediate began with occupations on high terrains that continued inhabited over the next period, thus becoming into a characteristic feature of Late Intermediate times.

The Inca Domain

The Incas incorporated the current Argentine Northwest Territory to the Tawantisuyu during the middle fifteenth century, as recorded by Spanish chroniclers and confirmed by radiocarbon dates. Calchaquí valleys were divided into two different provinces of the Collasuyu: *Chicoana* and *Quire Quire* (Tarragó 1984; Lorandi 2000; Williams 2004). The Inca domain in South Andes was based on the setting up of fortresses along the boundaries; the organization of state enclaves along the main road and secondary routes; the intensification of agropastoral, mining, and crafts activities; and the building of a network of sanctuaries at the peak of mountains as a way of appropriation of the religious local traditions previous to the Inca conquest (Williams 2004: 210).

When it comes to the establishment of government centers, the Incas built imperial compounds where no local settlements of Late Intermediate societies were previously erected. When populated settlements existed, Incas occupied limited sectors inside them. Lorandi considers that Inca domain on northwestern societies took place throughout *mitimaes* communities (foreign populations introduced in the area by the conquerors) that produced for the Inca. This implies that many of the local communities included along the conquested area might have never paid tribute to the Tawantisuyu (Lorandi 2000: 292). Williams points out that differences among the varieties of Inca settlements can be interpreted as expressions of different kinds of Inca domination: direct or interceded by the local elites. Thus the Inca marks over the landscape are in correspondence with the varying modes in which the state power associated with local populations (Williams 2004).

In Santa María valley, La Ventanita, located on Fuerte Quemado, constitutes an accurate example of a setting where local population included a specific sector for Inca administration. Williams (2004) considers that the site functioned as an imperial post. La Paya, in middle sector of Calchaquí valley, proportionates a similar case, though reduced to a unique compound constructed with clear Inca architectural technique: the red house (Williams 2004: 221; De Marrais 2001: 333). Not far from these sites, Guitian is a good example of a mix site (Inca-local) where the Inca sectors present wider dimensions, with a *kallanka* (big state house) clearly defined (Williams 2004: 221).

Among the entirely Inca sites, Potrero de Payogasta and Cortaderas stand out on the north of Calchaquí valley; Fuerte Tacuil in a lateral valley connected to Calchaquí and Punta de Balasto on the south end of Santa María valley are also remnants of exclusive Inca settlements (De Marrais 2001: 334–335; Williams 2004).

The objects that indicate the Inca presence in the region are the *duck-dishes* and the *aryballos* vessel type. These items presented a display of Incaic designs, but studies in the clays evidenced they were produced with techniques that corresponded with local traditions (Páez and Sardi 2014). Other northwestern ceramic styles that accompany Inca styles are Famabalasto black on red and polychrome Yocavil from Santiago del Estero, or the black on red urns where Belén and Santa María features were mixed (Marchegiani et al. 2009).

Hispanic Indigenous Contact

From the first entrance of Spaniards to Calchaquí region in 1535, conflicts between the newcomers and the inhabitants of the area took place. In 1557, the colonial authorities of Chile extended the occupation of the territory, capturing and then releasing the prominent leader that would give the name to the region: Juan Calchaquí, chief of Tolombón (Lorandi 2000). This authority led the destruction of the city of *Córdoba de Calchaquí* in 1562. Despite de indigenous resistance,

conquerors persisted with determination to take over the territories, subjecting the local populations to their personal requirements.

Between 1630 and 1643, the first generalized indigenous rebellion took place and was mitigated by a forced relocation of a great part of the communities away from their homeland. Thus, between 1643 and 1658, Jesuitical residences were re-established until the last outburst in 1659, commanded by the Andalusian impostor Pedro Bohorquez, who impersonated as the Inca king was accepted as leader by Calchaquí groups. The Spaniard governor Mercado and Villacorta needed to organise three military campaigns to subjugate the indigenous tribes permanently. The utmost resistance was carried out by the *Quilmes*, *Acalines*, and *Anghinhaos* and mitigated by the massive banishment of these populations to Buenos Aires, where they subsisted in a reduction for some time (Palermo and Boxaidos 1991). This way, Colonial period in the Calchaquí valleys did not begin until 1666 (Tarragó 1984).

Several testimonies related to settlement occupations and cemeteries from Hispanic-indigenous period account of a time span comparable in duration, to that of Inca domain. From this period, cemeteries as Caspinchango and Pichao in Santa María valley and Cachi Adentro in Calchaquí valley were registered (Tarragó 1984; Johansson 1996; Matera 2008). In Caspinchango cemetery, a Hispanic-indigenous context was isolated for the first time. The name of this location also refers to a group of ceramics with specific motifs and a characteristic form (cooking pots with foot) that perform as a diagnostic chronological indicator. According to the recent re-examination carried out by Matera, seven different kinds of burials existed, always located near cultivated fields and constituted by (1) grave goods with no association to particular individuals, (2) urns for the burial of children, (3) direct individual burials with no protection, (4) burials of individuals protected by stones that officiate as roofs, (5) pits with adjoining chambers, (6) cists or cylinder chambers with roofs on false domes and walls made of stone, and (7) urns inside rock structures (Matera 2008: 239–240).

In Amancay cemetery, located in Pichao, the burial patterning is constrained to two varieties: cists and ground burials. Inside the cists – which plan can be circular or rectangular – the presence of till 14 individuals of both sexes was registered inside a single structure (mainly adults but also young persons) together with pieces of objects made of iron, copper (bracelets), textiles, and glass beads along with ceramic recipients. Within a single structure, primary and secondary burials coexisted. The singular case of a direct burial was comprised by a single adult with grave goods alike the cist described above (Johansson 1996: 114–118).

In Cachi Adentro burials are individual, conformed by pits with lateral chambers, something exceptional along southern Andes (Tarragó 1984: 152).The graves for children, of smaller dimensions, are located between adult graves, containing under no circumstances burials in funerary urns. Among burial goods there were ceramic cooking pots with food remains and covered with bowls with their concave side up, attached to the mouths of the cooking pots with mud. Piles of bowls were displayed containing the ones on the top rests of food, bone arrowheads, or bundles of sticks. Occasionally these grave goods were complemented by spearheads, arrow shafts, objects of iron and copper, glass necklaces, arrows, and ochre (Tarragó 1984: 153). Other objects of European origin found inside some of the graves in Cachi Adentro are cow horns, chicken eggs, a belt buckle, and textiles (Tarragó 1984: 154).

In rock art depictions, the equestrian figure marks a clear chronological indicator. A rider on his horse leads a group of *llamas* – probably portrayed during pre-Columbian times and repainted during Hispanic-indigenous times – on Las Planchadas rock shelter, located in Guachipas, Salta province (Podestá et al. 2005: 45).

Archaeological Heritage and the Current Re-emergence of Indigenous Identities

Calchaquí wars shaped an empty remaining space caused by the banishment of local societies that soon began to repopulate the area under the *encomienda* system. This way some native people were sent back to work on plantations as well as indigenous that escaped from Tucumán returned

to their former territories. The valleys also received indigenous peoples proceeding from some other South Andean localities, as in the case of populations from Atacama (Lorandi 2000: 322–333; Rodríguez 2008).

Nowadays, a revival identity process began to emerge after a sustained rejection of indigenous traditions, embodied by resistance mobilizations that took place during 1960s and 1970s. Neoliberal policies along the 1990s caused the weakening of Argentine government power propelling empowerment processes then fostered by national administrations between the 2000s and the first half of 2010s.

"La Ventanita" site of Fuerte Quemado can be taken as an enlightening example of the gestation of the identity processes in Santa María valley. On the top of the hill, a door or a window frame made of stones stands out on the landscape attracting many visitors especially for the celebration of *Inti Raymi*, the *quechua* ritual carried out on the winter solstice. The construction of this landmark is attributed to the ancestors. Archaeological fieldwork allows sustaining that it was built over the founding of an ancient structure in early twentieth century that might have worked in pre-Columbian times as a solar clock. La Ventanita has become over the last decades into a symbol widely spread along Santa María urban architecture. Also public monuments inspired by the well-known Santa María funerary urns were erected, and each day more building projects are constructed according to indigenous methods. Combined techniques and designs belonging to indigenous, colonial, and peasant traditions are displayed along the landscape of the region, mainly in the localities of Amaicha del Valle and Colalao del Valle (Tucumán), Santa María (Catamarca province).

Transformations of the urban landscape inspired by the indigenous traditions take place parallel to the claims for the restitution of ancestral lands.

Santoro, Calogero M.

Daniela Osorio
Institute of Archaeology, University College London, London, UK
Laboratorio de Arqueología y Paleoambiente, Instituto de Alta Investigación, Universidad de Tarapacá, Arica, Chile

Basic Biographical Information

Calogero Santoro (Fig. 1) was born in 1953 in Antofagasta in Northern Chile, and when he was a teenager, he moved with his family to live in Calama, both cities located in the Atacama Desert. The experience of growing up in this uniquely hyper-arid landscape was a key to the passion he developed in later life, for researching the societies that had inhabited this harsh environment in the past.

In Calama, Calogero attended public elementary and high school and became familiar with the traditions of the indigenous Atacameño people. In this diverse cultural atmosphere, he remembers listening to public talks given by the pioneer archaeologists Father Gustavo Le Paige and Lautaro Núñez late in the 1960s, which fired his interest in the science of archaeological discovery.

In 1972, he entered the archaeology undergraduate program at Universidad del Norte in Antofagasta. Two years later, he was invited to participate in the Field Restauration Archaeological Project at Orongo ceremonial center, in Easter Island, directed by William Mulloy. This led him to discover the importance of rigorous long-term field studies and collaborative teamwork in archaeology. Four years later, in 1976 and while only 23 years old, Calogero became a faculty member of the Universidad del Norte, converted later in Universidad de Tarapacá.

Calogero obtained his bachelor's degree in 1980, which included preparing a dissertation on the formative period burial site of Azapa-71. Motivated to improve his archaeological knowledge, he applied successfully for a Fulbright Fellowship, for a master's Program at Cornell University in the United States. He moved there in 1985 with his two young daughters. Tom Lynch guided his master's thesis, focused on the archaic high Andean occupations of northernmost Chile.

Between 1987 and 1991, and with the support of FONDECYT (the main program of the Chilean Science Foundation), Santoro collaborated with specialists in paleoecology and paleobotany and with Marvin Allison, who was undertaking paleopathological studies on how social patterns played a role in health conditions of pre-Columbian societies. Subsequently, he undertook his doctoral studies at the University of Pittsburgh, funded by the Heinz Foundation under the supervision of Marc Berman. His thesis, focused on characterizing and explaining how local societies from a coastal valley of Northern Chile interacted with larger central Andes polities, like Tiwanaku and Inka states, has been recently published as a book (Santoro 2016).

Today, Calogero Santoro is a full professor at the Instituto de Alta Investigación, which is for senior academics from the Universidad de Tarapacá. In 2010 Calogero created the Laboratory of Archaeology and Paleoenvironment at this institute, where several graduate and postgraduate students, as well as senior researchers from both disciplines, undertake a range of research on the past cultures and environments of the Atacama Desert.

From 1989 to 2013, Calogero was the editor of Chungara Revista de Antropología Chilena, which is an internationally highly regarded peer-

Santoro, Calogero M., Fig. 1 Calogero M. Santoro at the National Museum of Australia, Canberra, 2007. (Photo courtesy of George Serras)

reviewed journal for American archaeology and anthropology. From 2002 to 2011, Professor Santoro was the scientific director of the Research Center for Desert People in Arica, Chile, which he helped to form.

Major Accomplishments

The bachelor thesis of Calogero, with the advice of Lautaro Núñez, led to a longer-term study of a pre-Columbian funerary site with more than 400 burials, which was supported by a National Geographic fund granted to Marvin Allison. The results were summarized in three journal papers and several presentations at national and international conferences (Santoro 1981). Simultaneously, Santoro initiated a project on the "Highland Archaeology of Northernmost Chile" which focused on the adaptations of prehistoric hunter-gatherers in the high Andes and their rock art (Santoro and Dauelsberg 1985). In the course of this pioneer fieldwork, several archaeological sites were discovered in the high Andes dating to the Early, Middle, and Late Archaic (Fig. 2). Prior to this field research, it was thought that early prehistoric populations may not have inhabited these high-altitude environments. The critical and in-depth analysis of these localities was the basis for his master's thesis, which was subsequently transformed into one of his most frequently quoted papers on the Archaic period in the high Andes (Santoro and Núñez 1987). In this interdisciplinary paper, which used paleoenvironmental and ecological data, ethnographic information, and archaeological evidence, Calogero established an interpretative model that is still used for reconstructing the mobility of the Andean hunter-gatherers of the dry puna (Osorio et al. 2017).

The cutting-edge interdisciplinary and methodological approaches used in this study have been characteristic of all his work, from his field research on the earliest peopling of the Atacama Desert (Santoro and Latorre 2009), to his studies of longer-term cultural processes among hunter-gatherer societies, to his research on the development of later prehistoric farming societies through to his work on the Inka period (Santoro et al. 2017; Santoro and Uribe 2018). In his scientific studies, Santoro has explored all the ecological zones of northernmost Chile, and this has involved a wide range of methodological and theoretical approaches and working with different archaeological data sets including lithic, pottery, botanical, faunal and human remains, ethnohistorical data, textiles, and rock art. This last topic has been undertaken in collaboration with his partner Daniela Valenzuela.

Santoro, Calogero M., Fig. 2 Calogero in the rock shelter Puxuma, one of the archaic sites founded during his highland project, at the end of the 1970s

Calogero has been supported by grants from the National Geographic, FONDECYT, the Wenner Green Foundation, PAGES (Past Global Chances), Fundación Andes, CONICYT (Chilean National Science Foundation), FONDART (National Art Foundation), and Mecesup (Education Ministry of Chile). He has also received fellowships from the Fulbright and Heinz Foundations, the National Museum of Natural History in Washington, DC, the American Museum of Natural History in New York, Dumbarton Oaks, the Endeavor Award from Australia, and the Chaire des Amériques of L'universite Rennes 2 in France.

His scientific productivity has been linked with a strong commitment to share and update archaeological knowledge through working with new generations of young professionals as well as senior colleagues from different parts of the world in the Americas, Europe, and Australia. His aspiration has been to use archaeological science as a context for flourishing international collaboration and friendship as well as for developments in archaeological research and understanding. This aim has taken him to participate in fieldworks in different regions of Chile including lately Patagonia, as well as Central Australia, South Africa, and Namib Deserts. He has advised graduate students and taught at universities of Argentina, Bolivia, Peru, Australia, the United States, and France.

In his fieldwork and academic activities, Calogero has strived to involve the indigenous communities of Northern Chile in the reconstruction of the past. He has offered talks and courses on the prehistory of the Andes and Atacama Desert to the general public, to archaeological tour guides, to school and university students, as well as to local indigenous communities (Fig. 3). He has always been willing to contribute to local and national newspapers and radio shows, in order to build a bridge between the latest scientific research and broader society. He has collaborated with television programs on the Discovery Channel, the National Geographic, BBC, La Tierra en que Vivimos, Al Sur del Mundo, and Catalyst of Australia, among others. These have been instrumental in highlighting Northern Chile as an area where interdisciplinary scientific teams have reconstructed long-term developments through prehistory in this unique region of South America. This includes evidence of the world's earliest

Santoro, Calogero M., Fig. 3 Calogero giving a public talk in the archaeological site Pukara Copaquilla, in 2003

human artificial mummification in the context of the Chinchorro culture of northern coastal Chile (Santoro et al. 2012; Standen et al. 2014).

Sarianidi, Victor I.

Vladimir I. Ionesov
Department of Theory and History of Culture, Samara State Academy of Culture and Arts, Samara, Russia

Basic Biographical Information

Victor Ivanovich Sarianidi is a famous Soviet and Russian archaeologist. He was born in September 1929 in Tashkent. In 1952, he graduated from the department of history of the Tashkent State University. For more than 50 years, Victor Sarianidi worked at the Institute of Archaeology in the Academy of Sciences.

The archaeological activities of V.I. Sarianidi started from participation in the excavation of the observatory of Ulugbek in Samarkand (Uzbekistan) in 1948, which was his first field expedition. Since then his life has been devoted to studying Central Asia.

In 1949, still being the student, V.I. Sarianidi started to work in Turkmenistan. As a graduate student, he was already taking part in archaeological expeditions in Uzbekistan and Turkmenistan. Later, he participated in the excavation of such monuments that are known nowadays as Togolok, Takhirbay, and Yaz Dep (1955–1956). In 1959, he joined the Institute of Archaeology in the Academy of Sciences of the USSR in Moscow.

From 1969 to 1979, V.I. Sarianidi participated as a leader (together with I.T. Kruglikova) in archaeological excavations in Northern Afghanistan. There he discovered monuments of the Bronze Age for the first time.

In 1975, V.I. Sarianidi defended his doctoral thesis on the topic of "Afghanistan in Bronze and Iron Ages" and was granted the full degree of Doctor of Historical Sciences.

From 1980 to the present, he has conducted very fruitful archaeological works in Turkmenistan on settlements and burial grounds of Togolok, Gonur-depe, and other objects.

Major Accomplishments

Thanks to V.I. Sarianidi's excavations (1969–1979) on the early urban settlements and burial grounds (archaeological group of Dashli monuments), the new center of agricultural civilization was revealed in Bactria.

He discovered the remains of a Bronze Age culture in the Karakum Desert in 1976. The culture came to be known as the Bactria-Margiana Archaeological Complex.

From 1978, under his supervisor, he organized the archaeological expedition excavating the royal necropolis Tillya Tepe of the early Kushan period. More than 20,000 golden objects were found in this necropolis. He also discovered six undisturbed tombs at Tillya Tepe, dating to the first century BCE. The deceased were richly equipped with the so-called Bactrian Gold.

By 1990 in the ancient delta of the Murghab River, he opened no less than 200 separate settlements of an Epoch of Bronze and the Early Iron Age – so-called the country Margush. Since 1974, V.I. Sarianidi has continued to carry out excavation of the capital city of this country Gonur-depe.

Sarianidi has also been excavating Margiana (Turkmenistan) since 1972. There he found a previously unknown civilization of the late Bronze Age. During the many years, his expedition's works have been concentrated on the urban necropolis Gonur. For 10 years from 1996, V.I. Sarianidi excavated the Gonur's Big Necropolis, where almost 3,000 burials and thousands of valuable artifacts were discovered.

Victor Sarianidi is a Doctor of Historical Sciences at the Institute of Archaeology in Moscow and an honorary member of the Greek Anthropological Society. He is the author of more than 20 books and 200 articles published both in Russia and abroad.

Sasanian Empire, Archaeology of the

Alan Farahani
Ancient History and Mediterranean Archaeology, University of California, Berkeley, CA, USA

Introduction

The Sasanian Empire was the last polity headed by an Iranian dynasty to rule from the geographic entity known as Iran before the advent of Islam, from 224 CE to 651 CE. At its height under Khosrow II in the early seventh century CE, its territorial extent encompassed many of the countries of the Middle East, Central Asia, and the Eastern Mediterranean. Over these 400 years, the political, ethnic, and religious composition of the empire changed continuously, and partly as a consequence of its location, the Sasanian Empire was involved in successive military confrontations with the Roman Empire on its western border, as well as with seminomadic peoples in various locations, including the Caucasus, Central Asia, and the Arabian Peninsula. Notwithstanding this sporadic but ever-present pattern of conflict, this period also witnessed the acceleration of a trend of interregional economic connectivity, especially between Chinese polities to the east and the Roman and then Byzantine Empire to the west. While this complex economic network often tends to be described in simplified terms as trade across a single "Silk Road," it underscores, in fact, a legacy of economic connectivity that intensified during this period.

Compared to its peer western and eastern polities, archaeology has played a relatively minor role in the interpretation of the Sasanian world. Literary sources in Greek, Latin, Middle Persian, Arabic, Syriac, and Armenian continue to inform a chiefly philological (and less often, historical) perspective. A significant portion of prior archaeological research focused on the analysis of monumental architecture, epigraphy, rock reliefs, and elite art objects. While noticeable advances in each of these areas have formed a more nuanced understanding of Sasanian royal culture and history, archaeological excavation has not enjoyed the same level of influence in reconstructing the daily lives of the majority of the empire's inhabitants. In addition, excavations of Sasanian sites in the early twentieth century did not employ contemporary scientific methods (cf. Huff 1987), which has hindered to some extent the reanalysis of material remains of Sasanian date. The sheer size of the empire, stretching across the boundaries of many separate modern countries, has also done much to complicate detailed investigation. Prominent in this regard is the continued limited accessibility of "core" territories to nonlocal archaeologists.

Despite these challenges, archaeological research has provided an unparalleled glimpse into many aspects of Sasanian imperial and domestic life that have often escaped notice in the literary record. These include the physical conditions of cities, agricultural intensification, variability in religious practice and ideology, and

details of the governing imperial bureaucracy. Ongoing and new archaeological research in the "periphery," such as in Central Asia, Arabia, and the Caucasus, has shed light on the social and ecological complexities of life on the frontier. The main contribution of more than a century of archaeological research has been recognition of the material heterogeneity of the empire. This extends to a wide variety of objects such as ceramic vessels, seals, coins, and textiles. Indeed, as many historical assessments of the Sasanian world emphasize a high degree of centralized political authority that was undoubtedly present, archaeological research may be said to have revealed a dynamic dialogue between local and external influences.

Definition

The political history of the Sasanian Empire begins with Ardashir I (224–241 CE), a vassal of the Parthian king Artabanus IV (216–224 CE), who rose in rebellion in the region of Fars in southwestern Iran. Ardashir marched against the Parthian monarch and defeated his army in the Hormozgan plain, an event that symbolized the toppling of the Parthian dynasty that had stood for close to four centuries (see Daryaee 2009 for a detailed social and political history). The victory was at once commemorated on a large rock relief at near Firuzabad, in which he and his son Shapur are shown unhorsing their Parthian opponents. In another investiture scene at Naqsh-i Rostam, famous for its monumental Achaemenian tombs, Ardashir is shown mounted and trampling on Artabanus. In the same relief, he receives the symbol of legitimate royal power, the *kydaris*, from Ahura Mazda, the supreme deity of Zoroastrianism, who himself is trampling Angra Mainyu.

The tradition of commemorating major political events on large rock reliefs and transmitting royal ideologies through them is a defining aspect of imperial practice for the first 100 years of the empire's existence. After Ardashir, the monarchs Shapur I (241–271 CE), Bahram I (271–274 CE), Bahram II (274–292 CE), Narseh (293–301), and possibly Ardashir II (379–383 CE) all commissioned rock reliefs whose meaning, content, and composition have been widely discussed. The construction of cities also became an enduring tradition, beginning with Ardashir's creation of a circular city named Ardashir Xwarrah (or "the glory of Ardashir") in Fars. Newly founded cities acted as spaces where Sasanian elites could create distinct imperial, urban traditions while engaging with perceptions of their own past (Canepa 2010).

In addition to rock reliefs, the early empire is marked by a large number of native Middle Persian inscriptions, especially by Shapur I, the son of Ardashir I, most notable for his success in a series of conflicts with the Roman Empire. In his third campaign, the Roman Emperor Valerian was captured, and this event was enshrined in rock reliefs at Naqsh-i Rostam and Bishapur, in Fars. Shapur I recorded these events in an inscription at Naqsh-i Rostam known as the "ŠKZ," or the Shapur inscription on the Ka'ba-ye Zardosht, a monument whose initial function is still debated. The inscription in question has been a key focus of scholarship for assembling a view of social and elite relations seen through the eyes of the imperial court. In particular, the hereditary, patrilineal nature of the monarchical system is stressed, though with significant acknowledgement of the elites of the empire. The dynamic relationship between regional elites and the monarch had significant long-term repercussions for the stability of the Sasanian polity as there were frequent struggles and negotiations between these two groups over political decision-making – to the extent that some monarchs were deposed by elite collusion and some elite social and political power was curbed by monarchical action. Other important epigraphic sources for this period include the Zoroastrian *mowbed* Kirdir's inscription at Naqsh-i Rostam and Narseh's (293–301 CE) inscription at Paikuli.

After the reign of Shapur II (309–379 CE), noticeable changes in imperial ideology are visible, especially through royal titles on coins. Yazdegerd I (399–420 CE) began to employ the title *ramshahr*, or "peace in dominion," perhaps to emphasize the end of recurrent military engagements with the Roman Empire. It is during the

reign of Peroz (459–484 CE) that new large-scale constructions appear in the archaeological landscape. It is argued that the construction of massive defense systems in the northwest and northeast might have begun in this period due to conflicts with seminomadic peoples. Under Kavad (488–531 CE), adjustments to the imperial bureaucracy continued, as are visible in offices with new seals, changes in coinage, and military positions. For instance, the internal division of the Sasanian Empire initially seems to have been organized around provinces encircling a provincial capital, perhaps from the reign of Kavad, the empire seems to have been quadripartitioned with an elaborate political apparatus established to oversee the fiscal and political governance of these areas (Gyselen 2001).

By the mid-sixth century, military conflict with the Byzantine Empire flared, although defenses against different groups passing through the Caucasus, were sometimes maintained with economic assistance from the Byzantine state. Under Khosrow I (531–579 CE) and especially Khosrow II (590–628 CE), the empire reached its territorial zenith through a series of initially successful, but ultimately ineffective, military campaigns that led the Sasanians to dominate the Eastern Mediterranean and Egypt for over a decade in the early seventh century CE. Architectural evidence such as that supplied by the palace at Taq-i Kisra near Ctesiphon and the rock relief grotto in Taq-i Bostan marks this political ascendancy. The empire began its collapse under Yazdegerd III (632–651), who fled in the face of encroaching, victorious Arab armies until he was eventually murdered in Merv. Although the empire ended as an autonomous political entity, the imprint of its ideologically imbued material trappings reverberated for centuries in the region, above all in its agricultural technologies, architecture, art, coinage, and everyday goods.

Key Issues/Current Debates

Agricultural Intensification

Most of the available archaeological evidence collected over the past 100 years points to a substantive trend of agricultural intensification during the Sasanian period. In some areas it represents the apogee of premodern intensive land use. Physical evidence for the maximization of agricultural output is provided by irrigation canals, dams, and weirs. Differentiating early Sasanian (third to fourth century CE) from late Sasanian (fourth to seventh century CE) irrigation canals remains, however, a problem exacerbated by the frequent reuse of these structures well into the Islamic period. Nevertheless, massive canals, such as the Nahrawan canal that diverted water from the Tigris River, attest to the impact of Sasanian imperial initiatives on the landscape. Initial and influential research in the Diyala region locating its dense, crisscrossing canals has shown that during the late Sasanian period, almost all of the cultivable land on the Lower Diyala was exploited. Improved imaging technologies and resolution have permitted identification of the density of these irrigation networks. CORONA satellite imagery has revealed a complex network of feeder canals and rectangular fortified sites in the Mughan Steppe in Azarbaijan (Alizadeh and Ur 2007). Elsewhere in Mesopotamia, shuttle radar topography has further elucidated the complications that beset Sasanian-period engineers who had to enlarge existing canals and build new ones in a landscape that had been irrigated since the third millennium BCE (Hritz and Wilkinson 2006).

A sophisticated series of drop-mill towers positioned at regular intervals at the edge of a rocky piedmont in the Deh Luran plain in south-west Iran illustrates the technological changes that accompanied new production initiatives (Neely 2011). Nearby, a dam bridge across the Karun river in Shushtar (Khuzestan), attributed to the early Sasanian period, was constructed to feed two major canal systems. Careful management of hydrological resources is evident at urban sites such as Gondeshapur and in military settings, where soldiers manning the Gorgan Wall maximized their ability to draw water from the Gorgan river in order to build canals for irrigation or to support construction projects. Settlement surveys in core political territories of the empire (discussed below) illustrate a marked quantitative

increase of settlements during periods of Sasanian intervention, especially in the late Sasanian period. Pollen cores have provided direct evidence for vegetative transformation in the landscape with significant increases in the cultivation of *Vitis* (grape), *Olea* (olive), *Juglans* (walnut), and other economic species (Djamali et al. 2009). Archaeobotanical reports from Merv from late Sasanian levels also indicate the cultivation of cotton (*Gossypium* sp.), a key for trade in textiles. A late Sasanian burial repository found in Shahr-i Qumis reflects these changes in burial practices, as the bones of an individual were interred with an entire pomegranate, almonds, and patterned cotton textiles.

The degree to which this intensification of production was overseen by the Sasanian state or initiated by local communities has yet to be resolved. There are some indications that the Sasanian state directly oversaw and stimulated the intensification process. For instance, a clay bulla from Veh-Ardashir yields an inscription stating it to be "the king's canal of Valashabad. . .of Veh Ardashir," and another bulla of the late Sasanian period mentions a "chief of the cultivators." These objects hint at the involvement of state authorities in the construction of new irrigation structures and in wide-scale agricultural production.

Economic Intensification

To a large extent, the trend of agricultural intensification was part of a larger process of interregional economic intensification. The archaeological data for Sasanian economic intensification can be divided into two categories: coinage and durable media. The main proxy for identifying trade during this period is the geographic distribution of Sasanian objects, especially coins, far outside the limits of their constituent territories. Researchers in China have documented almost 2,000 (on some counts) Sasanian silver coins at sites throughout China, with western China (Dunhuang, Chang'an) prominent. The contexts in which these coins are found include coin hoards, burials, and even decoration on furniture (Li 2004). The distribution, the eastern origin of the mints, and the appearance of these coins beginning with Shapur II onward (c. 300–650 CE) point to the eastward economic networks that developed in the early Sasanian period and which became more established with time. The distribution of glass goods is also correlated with coinage both spatially and temporally – glass objects of Sasanian manufacture found at Chinese sites appear in fourth century contexts and are found in greater concentration thereafter. An indication of imperial concern for the glass trade is validated by chemical composition studies of glass from Veh-Ardashir in Mesopotamia which illustrate differing sand types utilized after the fourth century CE to increase the quality of the glass.

It is important to note that the Sasanians were probably not directly engaged in this easterly trade in most instances. Excavations at archaeological sites in Central Asia, aided by the discovery of documents known as the "ancient letters," have shown the importance of the Sogdians, an Iranian-speaking people of western Central Asia, as traders and trade intermediaries within these economic networks (de la Vassiere 2005). At Merv, a sixth- to seventh-century CE structure was found containing Bactrian, Sogdian, and Middle Persian ostraca, a testament to the heterogeneous multilingual and multiethnic trading world of Central Asia of which the Sogdians and Sasanians were a part. Nevertheless, there were also direct contacts with Persian merchants, especially in later periods. A bilingual Chinese–Middle Persian inscription in Chang'an, China commemorating the burial of a Sasanian elite represents the outcome of already long-standing contact.

Overland routes were complemented by sea trade that originated in the Persian Gulf. Both ceramic and numismatic evidence attest to increased trade with South Asia, perhaps in direct competition with Roman trade emanating from the Red Sea. Ceramic vessels such as "torpedo jars" found in Pattanam in southern India, along with Roman and Sasanian coins, reveal a brisk exchange that began in the late fourth century and continued until the seventh (Tomber 2007). The analysis of bitumen-coated vessels from nearby Sri Lanka has been able to identify the source of

the bitumen; vessels dating from the third to ninth century appear to have originated near Susa in south-west Iran. The circumscribed nature of this resource pool indicates probable imperial involvement or craft communities in long-distance trade ventures.

Toward the west, Sasanian coins have been found in Roman and Byzantine contexts, even in more "remote" areas such as the Southern Levant. A coin hoard found in Humayma in Jordan contains potentially Byzantine counterfeit and Sasanian coin types. Based on the mark of the official Susa mint, the excavators concluded that the individual(s) carrying these coins and jewelry probably originated outside the limits of the Byzantine Empire (and perhaps within the Sasanian Empire). Other evidence in the Southern Levant points both to the paucity of objects of Sasanian manufacture in the Byzantine world and also the late date at which they begin to appear. In general, trade with the Roman and Byzantine empires has been less visible and less discussed. Apart from literary references to specific trade points such as Nisibis after its incorporation into the empire by Shapur II in 364 CE, Roman coins found as far east as Merv, and Byzantine coins found distributed throughout China, undoubtedly show that the Sasanian world acted as an economic intermediary and that frequent nonimperial economic transactions between these two polities were not an irregular phenomenon.

Border Defense

A complex system of border defense, especially in the northern boundaries of the empire, was initiated in the latter part of the Sasanian period. The longest extension of these structures stretches in an arc from the west to the east of the Caspian Sea. Construction of these massive walls seems to have been due to pressure from both sedentary and seminomadic people to the north, as well as the economic and ideological ambitions of the Sasanian imperial elite in these areas. The Derbent Wall is a massive fortification complex that is 50 km in length and stretches from the western littoral of the Caspian Sea westward through the central mountain range ("Dag Bary") of Dagestan, Russia. In some places the fortress walls in the city of Derbent reach 18 m in height. Middle Persian inscriptions on the walls of the fortress have formed the main criterion for dating its construction, which range from the fifth to the seventh century CE. An earlier mud-brick wall immediately to the south in Northern Azarbaijan known as Ghilghilchay ("clay wall") has been recently identified, perhaps dating to the sixth century, and itself stretches 60 km in length from the Caspian to the Caucasian interior.

To the east of the Caspian Sea, archaeological research has confirmed the presence of a formidable wall which was thought to date to the Parthian period, if not before (reflected in its Persian name, Sadd-i Iskandar, or "Alexander's Barrier"). A nearly 200-km-long wall, around 2 m in width, stretches from the Caspian Sea to the foothills of the Elburz in the east (Rekavandi et al. 2008). Recent studies of the Gorgan Wall have revealed a microcosm of Sasanian military life on the frontier as a series of forts, almost 40 in number, span the entirety of the wall, alongside barracks that may have housed as many as 20,000 soldiers. Numerous brick kilns point to the way in which Sasanian soldiers used available resources, especially local hydrology, in site maintenance on the frontiers. Radiocarbon and OSL dating indicate construction took place between the fifth and sixth centuries CE, which corresponds, in part, to literary sources that link its construction to the Emperor Peroz's (459–84 CE) conflicts with the Hephthalites. Other fortified structures such as the fortress at Turang Tepe and a fortified farmstead at Geotchick Tepe argue for the importance of the protection of this frontier zone.

Non-frontier fortresses imply that the Sasanian state was highly involved in maintaining control in the interior as well as along its borders. Ardashir and Shapur constructed numerous fortifications, in order to secure strategic positions in political centers both before and after full independence from their Parthian overlords. Other sites with notable fortifications include the port city of Siraf, where a large Sasanian-era barracks was identified in the early 1970s. The capital city Ctesiphon was also well fortified with massive walls 10 m wide. Despite literary references to a wall built in the southwest corner of the empire

meant to deter Arab tribes, no traces of such a constrution have yet been observed on the ground.

Urbanization

An explosion of urban and village construction occurred during the Sasanian period. The factors that led to this quantitative increase are still debated, but both ideological and environmental hypotheses are suggested. Settlement data from archaeological surveys have revealed how densely settled the empire was; it has been calculated that 75% of the Lower Diyala in Mesopotamia was occupied by urban sites larger than 10 ha (Adams 1981). Yet this phenomenon seems to have been regionalized, as surveys in other areas, such as near Susa, show a contraction of the total area occupied by settlements in the Early Sasanian Period (Wenke 1975–6), while the Bushehr region near the Persian Gulf shows a marked density of Sasanian-period settlements.

Royal patronage of urban construction is visible in the names of many of the cities themselves. Veh-Andiyok-Shapur, later Gondeshapur, is named after Shapur I's successful capture of the Roman city of Antioch, and excavations have revealed that its foundations are not preceded by prior settlement. Numerous new large cities dotted the landscape, above all in the region of Fars and to some extent in southern Mesopotamia. Cities such as Ctesiphon were expanded by the Sasanians, and in the case of Veh-Ardashir, new settlements were constructed adjacent to cities established in the preceding Seleucid and Parthian periods. Seals and bullae also reflect administrative changes that came with new urban priorities, such as specific offices for cities and territories like the *amargar* ("accountant"), who seemed to oversee financial transactions in them.

Less intensively studied have been the ramifications of life within and outside urban spaces in this period (Simpson 2008). Excavations in the 1960s and 1970s in Ctesiphon yielded a complex system of alleys, domestic structures, and activity areas. Ovens and querns are present in some rooms, and one excavated quarter of Ctesiphon yielded evidence of concentrated artistic production. Many alleyways were covered by a combination of clay and bitumen, making drainage of seasonal rainfall difficult. Using comparative evidence from Merv, it has been argued that this may have caused significant urban pollution in the form of runoff. In Merv, no door hinges were found (unlike in Ctesiphon), implying that the denizens of Merv during the Sasanian period covered their doorways with soft material. The material conditions of these cities should be contrasted with royal centers such as Bishapur, Firuzabad, and Istakhr, where evidence for domestic, nonelite life is less pronounced. Even in Fars, a considerable degree of heterogeneity is encountered in elite residential structures, such as can be seen in the mid-fourth-century-CE manor house at Hajiabad, where elaborate idiosyncratic stucco decorations point to negotiations of the ruling elite with individual expression (Azarnoush 1994).

The Impact of the Sasanian State on the "Periphery"

Identifying the material impact of the Sasanian state on areas beyond its nominal core, namely, Fars and Khuzestan, continues to be an area of debate for archaeologists and historians. In northern Mesopotamia, despite the presence of a large number of ceramic vessels (themselves diverse in style and decoration) from a range of archaeological sites, architectural evidence for an imperial presence is still lacking. In southern Iraq, excavations at Hira in the early 1930s revealed the center of the important sixth- and seventh-century CE client kingdom of the Lakhmids, who were formally incorporated into the empire by Khosrow II. Yet the excavators were unable to locate any diagnostically Sasanian objects or stratigraphic levels and tentatively associated the earliest Sasanian intervention to the latter half of the empire's history (sixth to seventh century). This is compounded by the continued lack of a formal ceramic typology from the "core" Sasanian territories and regional affinities in ceramic styles. The debate concerning the timing and intensity of the Sasanian presence in Arabia (Eastern Saudi Arabia, Bahrain, and the UAE) continues, with scholars arguing that despite Sasanian epigraphic claims to early control over this area, archaeological evidence is lacking.

In the north, aside from the impressive fortifications of Derbent with unequivocal attachment to the Sasanian state, evidence for changes in daily life is more difficult to detect. A decade of excavation at the site of Dvin, Armenia, has yielded a large number of Sasanian artifacts, many of them dating to the *Marzpanate* period of Shapur II. One church that can be dated by excavations to the late fourth/early fifth century indicates that the local Christian identity was never wholly supplanted despite frequent Sasanian attempts to persuade the population of Armenia of this date to "return to" some form of Zoroastrian practice.

The eastern frontier of the Sasanian Empire has yielded evidence for the presence of imperial officials and their active involvement in daily life in these territories. The decipherment of Bactrian and the discovery of a trove of "Bactrian letters" have provided insight into the administration of an area where excavations have not been able to provide extensive archaeological data. An unambiguous reference to a Sasanian official in these letters dates to the late fourth century, where a nonofficial refers to a "satrap," or governor of Bactria, which is in agreement with a bulla bearing the title of a "satrap" of Balkh in Bactrian and Middle Persian. Another letter refers to a "fortress commander," emphasizing the commercial and military interventions brought about by Sasanian involvement. A recently discovered monumental rock carving at Rag-i Bibi in Afghanistan, Sasanian in style but with local Kushan themes and fauna (such as the royal hunt of a rhinoceros), demonstrates the diverse potentials for imperial and local interaction.

Religious Pluralities and Identities

Throughout the history of the Sasanian Empire, diversity between and within religions was markedly pronounced. Zoroastrianism was not alone, however, Christianity, Manichaeism, Mazdakism, Mandaeanism, Buddhism, and Judaism all had adherents at different times and places within areas of Sasanian political control. A host of other undocumented local traditions, beliefs, and practices probably existed alongside these traditions as well. Archaeological evidence for the development, presence, and variability in religious practice is seen in architecture, epigraphic remains, and domestic objects. The remains of fire temples, places of worship for Zoroastrian adherents, are found throughout the entirety of the Sasanian world. Architectural changes seem correlated to larger political changes, such as the *chahar taq*, or four-arch construction, which only appears during the Sasanian period. At Kuh-i Kwaja in Seistan, Sasanian builders added a *chahar taq* to the temple not long after their political ascendancy.

In addition to large Zoroastrian religious centers such as that at Takht-i Suleiman in Azarbaijan and a more modest temple at Turang Tepe near the Gorgan Wall, recently discovered fire temples contribute additional knowledge of Sasanian Zoroastrian practices. At Mele Hairam in southwest Turkmenistan, a fire temple with Sasanian occupation levels contains a fire altar whose enclosing room displays the floor plan of a *chahar taq* (Kaim 2004). The site of Bandiyan in Khorasan also possesses a fire altar housed inside a cross-shaped room (Rahbar 2008). Elaborate stucco reliefs depicting elite individuals are accompanied by inscriptions in Middle Persian. The extent to which the site of Bandiyan is a religious complex rather than a manor with religious edifices attached is still debated. The site, according to the excavators, was not sponsored by the ruling imperial authorities but instead looked to local architectural styles. The debate reflects a more generalized discussion concerning the precise function of reticular rooms in particular temples and whether fire altars can be connected to Zoroastrian rituals known from literary texts.

Royal patronage of many of these structures is nevertheless clear. Shapur I records his dedication to the maintenance of official fires in his ŠKZ inscription. Fire altars and their attendees are also prominently depicted on the obverse of Sasanian coins. Bullae record imperial offices such as the *mowbed mowbedan* ("priest of priests"), who seem to be standard functionaries in the provinces. Officials called *driyošan jadaggov ud dadvar*, or "judges and protectors of the poor," have titles

directly derived from the *Avesta*, the key religious text of the Zoroastrian community. These artifacts illustrate the entanglement of administration, ideology, and ethnoreligious rule throughout the Sasanian period.

Epigraphic information also shows that early Sasanian officials already had knowledge of some of the beliefs and practices of non-Zoroastrian adherents. The third-century inscription of Kirdir, the "court priest," beneath the ŠKZ, describes how he suppressed "Jews, Buddhists, Hindus, Nazarenes, Christians, Mandaeans, and Manichaeans." It is an explicit indication of the presence, or the perception of a presence, of these groups within the empire. An inscription written in Roman Dura Europos by a scribe of the invading Sasanian army records how he recognized in one of the synagogue paintings the "god of god of the Jews." Numerous personal seals of individuals with either traditionally Jewish names written in Hebrew, or with scenes from the Hebrew Bible, have been found at sites in Mesopotamia. Aramaic "incantation bowls" also found at a number of sites in Mesopotamia, decorated on the interior and lined with text written in Aramaic, Mandaic, Syriac, and Middle Persian, request physical outcomes in the secular world using a wide array of religious language (Morony 2007).

The existence of a Christian community in the Sasanian world increasingly became an ethnopolitical issue, to the extent that conflict with the Roman and Byzantine empires later involved the role of religion after the conversion of the Emperor Constantine I. Nestorian churches have been found both within Sasanian territory and within its sphere of influence, such as in Northern Iraq (Khirbet Deir Situn) and in the capital, Ctesiphon. Some seals display Christian names or portray Christian themes. In Merv a coin displays an image of the Emperor Yazdegerd I flanked by a cross and crescent with flying ribbons (Herrmann and Kurbansakhatov 1995). This underscores the fluid nature of royal involvement with religious communities and their self-representation. This became especially important as native Persians began to convert to Christianity – a Psalter written in Middle Persian found in the Turpan oasis in China is indicative not only of the routes through which religious communication flourished but also of a burgeoning need to communicate religious texts in local languages.

Future Directions

Archaeological research has enriched the perception of the Sasanian world and complicated attempts to portray it as a homogeneous whole. Many archaeologists have sensed a missed opportunity in terms of careful, scientific excavation that incorporates the full panoply of modern archaeological methods. The addition of environmental archaeological analysis, such as zooarchaeology and paleoethnobotany, in recent excavations has revealed important patterns in production and consumption during these periods of economic intensification. This coincides with a need for more excavation of domestic structures and residential sites, of which very little is known outside of scant remarks in literary sources. A strong theoretical framework for these inquiries could help generate hypotheses or provide the lenses through which more could be explored concerning gender, agency, and identity, especially the ways in which individuals or communities in this period negotiated the impact of Sasanian imperial interventions.

Sauer, Carl

Leandro Matthews Cascon
Faculteit Archeologie, Universiteit Leiden, Leiden, The Netherlands

Basic Biographical Information

Considered one of the most important geographers of the twentieth century, Carl Ortwin Sauer (1889–1975) was born on December 24 in Warrenton, Missouri (USA), a rural surrounding which he would recognize as an important influence in his interest in earth history (Parsons 2009).

Sauer was the grandson of German immigrants from Wurtemburg, and from the ages of 9–11, he lived in Southern Germany (Gade 2011). Back in his hometown, he later obtained his undergraduate degree at the Central Wesleyan College in Warrenton, where his father was a professor of French and Music (Parsons 2009; Gade 2011). After 1 year as a graduate student in geology at Northwestern University, Sauer was attracted to the geography program at the University of Chicago, where he obtained his PhD degree in 1915. It was also at this time of his life that he married Lorena Schowengerdt, a fellow student from Central Wesleyan College. The two would go on to share a relationship which would last until their passing away in the city of Berkeley in 1975, in which Lorena would pass away a month before Carl's death on the 18th of July (Parsons 2009).

Major Accomplishments

It was at the University of California's campus at Berkeley that Sauer conducted much of his work, from the year he began lecturing there in 1923 and past his retirement in 1957. Afterward, he continued to teach at Berkeley as Professor Emeritus and wrote four more books, one of these published posthumously (Parsons 2009). He is of fundamental importance in the establishment of what became known as the Berkeley School, a branch of geography known for its cultural and historical approach regarding environmental history.

Sauer's themes of inquiry, such as human dispersals, the domestication of plants and animals, and the origins of agriculture, were frequently of common interest to archaeology. Sauer's opinions regarding the relationships established between people and their environments would place him in an important debate with Herbert Joseph Spinden, a prominent archaeologist who in the second decade of the twentieth century published pioneering works on the origin of agriculture in the Americas.

Sauer criticized Spinden on what he would call a "potamic" theory for the origins of agriculture in the New World. Sauer did not believe that agriculture would have first been developed in an arid region with the necessary need for irrigation, and he believed that data such as that presented by Russian botanist Nicolai Vavilov on plant domestication centers around the world demonstrated that domestication would have first taken place in mountainous valleys, where conditions would favor the manipulation and experimenting of a variety of plants. Sauer also believed that Vavilov's work in plant biogeography, which pointed to various centers (also called hearths) of domestication in the New World, reinforced the idea of multiple and independent areas of agricultural origins in the Americas, and proposed the existence of a geographical pattern which indicated two great regions of plant domestication for the continent, roughly divided around Central America. To the north, seed agriculture (such as that of maize) would have been of major importance, while to the south root agriculture (such as that of manihot) would have been the major form of cultivation (Sauer 1952, 1963 [1936]).

Sauer's criticism regarding Spinden's hypothesis on agricultural origins in the Americas can be seen as more than a disagreement of various points, demonstrating in fact a fundamental difference between two distinct forms of understanding such phenomenon. If for Spinden agriculture originated in an environment which would have produced a *healthy but hungry population*, for necessity would be the *mother of invention* (Spinden 1920 [1915]), Sauer stressed out the importance of an idea of abundance in order to understand the same phenomenon, arguing that the development of domesticated plants through the process of the selecting of individuals with desirable characteristics would only have been possible in societies where, with no shortage of dietary resources, leisure time would have been available for the reflecting, experimenting, and discussing which is necessary in every process of invention, including that of plants. His unique thoughts on plant and animal domestication can be appreciated in his book *Agricultural Origins and Dispersals*, published in 1952 and which attempted to present a synthesis of Sauer's hypothesis and opinions on the subject.

Sauer's interest in the history of the dispersal of human and of cultivated plants in the past was shared by some of his students, as can be seen in the works of George F. Carter on human settlement of the Americas and of Carl Johannessen on the dispersal of maize (Gade 2011). His interpretation and that of his students regarding agricultural origins and human and plant dispersals did not always hold up in the face of new archaeological and genetic evidence, but his importance in integrating various lines of evidence in order to elaborate such interpretations cannot be underestimated.

Sauer's work has received uncommon attention since his death (Gade 2009). Out of hundreds of articles and chapters in which he is cited, about 70% of these were published after his passing (Denevan 2009) many times by non-geographers, including archaeologists. By defending the importance of tropical world regions and root crop agriculture in the

development of the origins of agriculture, Sauer's work was and still is influential for archaeologists working in tropical areas, for it demonstrates a sophisticated train of thought for which to think questions regarding settlement and subsistence of past populations in these contexts. Sauer's work has been an important point of reference for studies regarding agricultural origins and practices in precolonial Amazon, as can be seen in the work of Donald Lathrap and William Denevan.

In the course of his long and productive life, Carl Sauer advised over 30 doctoral dissertations students and published over 100 works, some of which can be seen in important compilations (see further readings).

Scandinavia and the Baltic Sea Region: Medieval Archaeology

Shane McLeod
The University of Western Australia, Centre for Medieval and Early Modern Studies, Perth, WA, Australia

Introduction

Scandinavia and the Baltic experienced significant change during the medieval period, including its perception by other European peoples. At the beginning of the period, it was a region largely unknown to the literate societies in the west. By the end of the medieval era, it was a known entity that had been largely integrated into the west European system both culturally and economically. This change occurred during three major periods of trade, cultural exchange, and armed conflict: the so-called Viking Age, which was centered in Scandinavia but also impacted upon other areas of the Baltic, the Northern Crusades, and the formation of the Hanseatic League.

Definition

The Middle Ages is a particularly problematic term for Scandinavia and the Baltic as both its

beginning and end are traditionally dated to events that occurred beyond this region. If the medieval period is considered to have started when the Western Roman Empire collapsed during the fifth century, then choosing a starting date for the Middle Ages in Scandinavia and the Baltic is highly problematic. Although items from the Empire reached northern Europe and occasionally men from Scandinavia and the Baltic served Rome as mercenaries, the region was never part of the Empire so there is no convenient starting date for the Middle Ages. However, the fifth-century migration period, during which groups described in classical sources as *gens* moved south, is often used. Many of these groups, including the Goths, Jutes, Angles, and Burgundians, traced their roots to Scandinavia (Hedeager 1992). The problem is compounded in the southern Baltic where the material culture of the Slavic people is trans-regional, making it difficult to break the early medieval era into periods (Urbańczyk 2008). Attempts at periodization are complicated further by the convention in Scandinavian scholarship for the Middle Ages to start at the end of the Viking Age, at around 1000 CE, when the kingdoms of Denmark, Norway, and Sweden (began to be) unified, Christianity made serious in-roads, and Scandinavia began to have its own, non-runic, written history. The end of the Middle Ages is equally problematic, as conventionally it ends with the start of the Renaissance, a cultural movement which arguably did not directly influence all areas of Scandinavia and the Baltic. For the sake of convenience, the Middle Ages will be taken as ending in c. 1500. Between these two end points, the medieval period up to c.1000 in Scandinavia and Poland and as late as 1200 elsewhere in the Baltic is divided into various sub pre- and proto-historic periods which are often named after developments further west. These terms often vary according to the country and include the Merovinger/Merovingian Period, Vendel Period, Iron Age, Germanic Iron Age, Late Roman Iron Age, Middle Iron Age, and Viking Age. As noted above, the chronologies of these sub-periods are not always well defined, but there is general agreement for the start of the Viking Age. Its traditional historical start is the Norse raid on Lindisfarne, England, in 793, although there is also a possible raid in Dorset, England, recorded in 787. Art historians concur, with the early Viking Age having a native animal ornament style (style E) that appeared from the late eighth century, at roughly the same time as the first raids. Individual sites, particularly those of the earlier period, are often difficult to date precisely unless dendrochronology is available, although the importation of such items as glass beakers, pottery, and especially coins do help in establishing a terminus post quem.
